ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupational Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc. For terms and further particulars apply to the Medical Superintendent (Telephone Nos. 2356 and 2357 Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, near EXETER,

Medical Students and Qualified Practitioners admitted to the Practice of this Hospital. Unusual opportunities are afforded of seeing Obstetric Complications and Operative Midwifery (about one half of the total admission being primiparous cases). Over 2,700 patients are admitted to the Wards annually, and in the Ante-natal department there are over 20,000 attendances per annum. Clinical demonstrations are given by the Staff daily.

For rules, fees, etc., apply H. B. STOKES, Secretary-Superintendent

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in April, 1938.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W. 1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than February 28th, 1938.

MINISTRY OF PENSIONS.

The Minister of Pensions proposes to appoint a limited number of MEDICAL OFFICERS to the ESTABLISHED STAFF of the MINISTRY for clinical and administrative duties either at Headquarters or in the Provinces, and applications are invited from registered medical practitioners (men) for appointment to these posts.

The scale of salary is £750 per annum, rising by annual increments of £30 to a maximum of £1,000. The appointments will be subject to the usual Civil Service conditions as to superannuation, etc.

Candidates must be registered medical practitioners of not less than five years' standing and have held House appointments in General (preferably teaching) Hospitals. Generally, preference will be given to those possessing University degrees in Medicine and Surgery.

It is desired that applicants should be not less than 35 years of age. Consideration will, however, be given to suitable candidates below this age, but if appointed, the entering salary in such cases would be proportionately reduced.

Successful candidates will be required to serve in the first instance in an unestablished capacity for a period of six months in a Ministry Hospital, at the expiration of which they will, if their service has been satisfactory, have to satisfy the Civil health, etc., before

of Parliament or in candidate liable to

disqualification. Applications must be made on forms which can be obtained from the Secretary (Establishments), Ministry of Pensions, 18, Great Smith Street, London, S.W.1.

The closing date for applications will be February 3rd, 1938.

CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE.

Withington, Manchester 20.

Applications are invited for the post of RESIDENT SURGICAL OFFICER at the above hospital, to commence duties immediately. The appointment is for a period of six months, but will be renewable. Previous resident appointments essential.

Salary, at the rate of £150 per annum, plus residence, board and laundry.

Applications, with full details of previous experience, together with copies of testimonials, should be sent to the Superintendent immediately.

THE ARMY DENTAL CORPS.

Applications are invited from dental surgeons for appointment to a limited number of commissions in The Army Dental Corps.

Candidates, who should not be over 35 years of age, will for the present be selected for commissions without competitive examination, but will be required to present themselves in London for interview and physical examination. They must hold the degree or diploma of a British University or College of Surgeons and be registered under the Dental Acts or Medical Acts.

Successful candidates will, in the first instance, be given short service commissions for six years, at the end of which period they will retire with a gratuity of £1,000, unless they have been granted permanent commissions. Permanent commissions will be given to officers selected from among those who wish to make the Army their permanent career.

Particulars, including Regulations for Admission, pay and allowances, and forms of application may be obtained on request either in writing or in person to the Director, Army Dental Service, The War Office, London, S.W.1.

LANCASHIRE MENTAL HOSPITALS BOARD.

BROCKHALL CERTIFIED INSTITUTION FOR MENTAL DEFECTIVES.

Langho, Nr. Blackburn.

APPOINTMENT OF DEPUTY MEDICAL SUPERINTENDENT.

Applications are invited for the whole-time appointment of Deputy Medical Superintendent at the above Certified Institution.

The salary is £750 per annum, rising by annual increments of £25 to a maximum of £850 per annum. An additional £50 per annum will be paid for the possession of a Diploma in Psychological Medicine.

The appointment will be subject to the provisions of the Asylums and Certified Institutions (Officers' Pensions) Act, 1915.

Applications are required to submit their applications on a form to be obtained from the undersigned and applications endorsed "Deputy Medical Superintendent" should be sent to or delivered at my office not later than 12 noon on Monday, February 7th, 1938.

Conveyance, either directly or indirectly, will be a disqualification.

GEORGE ETHERTON,
County Officer, Preston.
January, 1938

CITY AND COUNTY OF BRISTOL.

HAM GREEN HOSPITAL AND SANATORIUM.

JUNIOR ASSISTANT RESIDENT MEDICAL OFFICER (FEMALE).

Applications are invited for the post of Junior Assistant Resident Medical Officer (Female) at the Ham Green Hospital and Sanatorium, Bristol. The post is for a period of three years, renewable. The salary is £1,000 per annum, plus allowances. Applications should be sent to the Medical Officer of Health, Ham Green, Bristol.

COUNTY OF LANCASHIRE.

APPOINTMENT OF EAR, NOSE AND THROAT SURGEON.

The Health Committee of the County of Lancashire invite applications for the above appointment from a registered medical practitioner qualified to conduct a general practice and operative work at the Manor Hospital on a weekly salary of £200 per annum.

Applications to be sent to the undersigned not later than January 21st, 1938.
James A. M. Clark,
County Health Officer, Medical Officer of Health,
Warrington.
January 15th, 1938.

THE ROYAL INFIRMARY AND ROYAL HOSPITAL, Salford.

FRACTURE CLINICS.

Applications are invited for the posts of First Assistant in Orthopaedics and in Fracture Clinics. The appointments are for a period of three years, renewable. The salary is £1,000 per annum, plus allowances. Applications should be sent to the Secretary of the Royal Infirmary, Salford.

The salary attached to each post is at the rate of £150 per annum. Applications should be forwarded to the Secretary of either Hospital, from whom further particulars may be obtained if desired.
January 6th, 1938.

MASTERY OF MIDWIFERY

OF THE SOCIETY OF APOTHECARIES OF LONDON (M.M.S.A.)

The Mastery of Midwifery is designed to give evidence of intensive study and practical experience in Ante-Natal Care, Midwifery, and Infant Welfare and their relation to Hygiene and Preventive Medicine.

The Diploma of the Mastery indicates competence to undertake the responsible control of Maternity and Child Welfare work.

The tests imposed are stringent: the examination, written, oral and clinical, demands thorough and detailed knowledge gained by practical experience and constitutes a definite endeavour to combat Maternal and Infant Mortality.

Examinations are held twice yearly, in the months of May and November.

Regulations and forms of application for admission to the examination may be obtained from:—

THE REGISTRAR, The Society of Apothecaries, Water Lane, E.C. 4

THE LONDON SCHOOL OF DERMATOLOGY

St. John's Hospital for Diseases of the Skin,
5 Lisle Street, Leicester Square, W.C.2

Conducted by the Honorary Staff of the Hospital, together with the Physicians in charge of the Dermatological Departments of the London Teaching Hospitals. Lectures and Demonstrations twice weekly during October and November, and again during January and February, and four times weekly during May. General Practitioners desiring to attend any particular lecture or occasional lectures can do so without paying a fee. Clinics daily at 2 p.m. and 6 p.m. Saturdays 2 p.m. only. The Laboratory is particularly well equipped and arrangements can be made for classes. Individual instruction or for research work. Enquiries: The Dean or Secretary of the School.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, W.2

(University of London)

PRIMARY F.R.C.S. COURSE.

OLIVE FURNEAUX,
Secretary

BRITISH ASSOCIATION OF RADIOLOGISTS (FELLOWSHIP BOARD)

FELLOWSHIP EXAMINATION.

The second Examination for the Fellowship of the Association will be held in London during the period, November 28th to December 2nd, 1938.

The Examination is limited to Medical Practitioners who are duly registered in the country in which they practice, and who have held a recognised Diploma in Radiology for not less than two years. The Diplomas so far recognised are those granted by the following bodies: the Universities of Cambridge, Edinburgh, Liverpool, and London; the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England; and the American Board of Radiology.

The principal subjects of the Examination are:

I. RADIO-DIAGNOSIS.

II. RADIO-THERAPEUTICS.

Every candidate must pass, on an honours standard, the examination in either Radiodiagnosis or Radiotherapeutics. A candidate may, if he chooses, elect to take honours in both subjects. All candidates will also be examined in General Medicine, General Surgery, and General Pathology, but those who have passed examinations for higher medical or surgical qualifications may be exempted partly or wholly from this part of the Fellowship Examination. A thesis (or published work in lieu of a thesis) concerned with some aspect of their honours subject is also required from candidates. This thesis may be lodged with the Warden at any time after the expiration of two years from the taking of a radiological diploma.

In addition to passing the Examination, candidates must comply with the conditions for ordinary membership of the Association before they can be elected Fellows.

Practitioners intending to specialise in Radiology are invited to register their names with the Board, in order that they may receive information.

Entrance forms, which must be sent in before the end of August, 1938, and further particulars may be obtained from:

F. HERNAMAN-JOHNSON, M.D., D.M.R.E.,
Warden, Fellowship Board,
British Association of Radiologists,
32, Welbeck Street, London, W.1.
Telephone: WELbeck 6867.

AUCKLAND HOSPITAL BOARD, NEW ZEALAND.

THE AUCKLAND HOSPITAL BOARD INVITES APPLICATIONS FOR THE FOLLOWING POSTS:

1. RADIO-THERAPIST (X-Ray Therapy and Radium).

The successful candidate will be required to take full control of the Therapy Section of the Radiological Department.

The appointment is whole-time.

Salary will commence at £1,000 per annum, rising by annual increments of £100 to £1,200 per annum.

2. RADIOLOGIST (Diagnosis).

To take full charge of the Diagnostic Section of the Radiological Department.

The appointment is whole-time.

Salary will commence at £1,000 per annum, rising by annual increments of £100 to £1,200 per annum.

Preference will be given to candidates possessing the D.M.R.E. or equivalent qualification.

Full information and forms of application may be obtained at the office of the High Commissioner of New Zealand, 415, Strand, London, W.C.2

H. A. SOMMERVILLE,
Secretary.

Auckland, New Zealand
December 9th, 1937.

UNIVERSITY OF ABERDEEN. LECTURESHIP IN BACTERIOLOGY.

The University Court will shortly proceed to the appointment of a Lecturer in Bacteriology in the University of Aberdeen.

The salary proposed is £500 to £600 according to qualifications and experience.

Persons desirous of being considered for the office are requested to lodge their names with the Secretary to the University on or before February 18th, 1938.

The conditions of appointment and form of application may be obtained from the undersigned.

H. J. BUFCART,
Secretary to the University of Aberdeen
The University, Aberdeen.

LIVERPOOL DENTAL HOSPITAL, Pembroke Place, 3.

The Committee invites applications for the post of HON. ANAESTHETIST. Attendance, one half-day per week. Applicants must possess a medical qualification.

Further particulars may be obtained from the Hon. Director, by whom applications must be received not later than Wednesday, February 2nd 1938.

UNIVERSITY OF CAPE TOWN

SENIOR ASSISTANT IN ANATOMY.

The University of Cape Town invites applications for the post of Senior Assistant in the Department of Anatomy; salary £600 per annum, rising by annual increments of £25 to a maximum of £900 per annum.

Candidates must hold a medical qualification and should have had previous teaching experience. The successful candidate will be expected to undertake research work in addition to his teaching duties. Ability to teach in both official languages (English and Afrikaans) will be a recommendation.

Applications must reach the Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, London, W.C.2 (from whom forms of application (quadruplicate) and a memorandum giving the conditions of appointment may be obtained), not later than February 15th, 1938. Applicants, in addition to submitting copies of testimonials, must give the names of three referees, and must state the earliest date on which they would be able to assume duty.

GOVERNMENT OF BAHRAIN, PERSIAN GULF.

Qualified doctor required as GOVERNMENT MEDICAL OFFICER to take charge of new hospital, medical and surgical, village dispensaries and public health.

Age between 30-40, British born. Initial salary Rs. 1,400 per month, rising by triennial increments of Rs. 50 per month to Rs. 1,800 per month. (One rupee = 1s. 6d.) Provident fund Rs. 150 per month. Agreement in first place for five years. Leave after every two years' service at rate of 45 days for each year's service. Free passage on joining and once in every four years when proceeding on leave. Free furnished house and car.

Applications accompanied by copies of three testimonials to be sent by Air Mail to THE ADVISER, Bahrain Government, Bahrain, Persian Gulf.

CORPORATION OF KIRKCALDY. FEVER HOSPITAL AND SANATORIUM.

Applications are invited from registered medical practitioners for the post of RESIDENT MEDICAL OFFICER at the above hospital. The salary is £300 per annum, with board, residence and laundry. The successful candidate will be required to undergo a medical examination and to contribute to the Corporation's Superannuation Scheme.

Forms of application may be obtained from the Medical Officer of Health, Public Health Department, Kirkcaldy, to whom they should be returned, together with copies of three recent testimonials, not later than February 4th, 1938.

Kirkcaldy. WILLIAM HUTTON, Town Clerk.

LONDON COUNTY COUNCIL.

Applications invited from registered medical practitioners for inclusion in a panel for filling vacancies for temporary part-time assistant medical officers for school medical work. Rate of pay 30s. for a session of 22 hours.

Special experience of medical examination of children is necessary. Employment will depend upon the needs of the work, but ultimately candidates engaged will be expected to work three sessions a week during school terms.

Application forms (stamped addressed footsack envelope necessary) from Medical Officer of Health (S.D.S.), County Hall, Westminster Bridge, S.E.1, returnable by January 29th. Canvassing disqualified.

DERBYSHIRE COUNTY COUNCIL.

WALTON SANATORIUM, Near Chesterfield.

JUNIOR RESIDENT ASSISTANT MEDICAL OFFICER (Male).

Applications are invited for the post of Junior Resident Assistant Medical Officer at the Derbyshire County Sanatorium. Candidates with previous institutional experience of tuberculosis will be preferred, and practical experience of artificial pneumothorax work will be considered an additional qualification. Candidates must be single.

Salary at the rate of £350 per annum, rising by annual increments of £25 to £450 per annum, together with board, lodging, etc.

The successful candidate will devote the whole of his time to the duties of the Office.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the person appointed will be required to pass a medical examination.

Application forms may be obtained from the undersigned, to whom they must be returned, together with copies of not more than three recent testimonials, on or before January 20th, 1938.

W. M. ASH, County Medical Officer.
New County Offices, Derby.
January 31st, 1938.

COUNTY BOROUGH OF ROTHERHAM.

Obstetric Medical Officer and Deputy Medical Superintendent, Alma Road Hospital.

Applications are invited from fully qualified medical practitioners for the post of Obstetric Medical Officer and Deputy Medical Superintendent at the Alma Road Hospital, Rotherham, at a salary of £750 per annum, less emoluments to the value of £85.

Candidates must be qualified registered medical practitioners and must have held previous resident appointments in maternity hospitals, and have had experience in ante-natal work.

The officer appointed will be responsible for the obstetric work at the Alma Road Hospital and at Ferham House Municipal Maternity Home, and in addition will be required to undertake duties in the ante-natal, post-natal and gynaecological services, organise the maternity emergency service and assist in the supervision of the district midwives service and other duties assignable to midwifery.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination as to physical fitness.

The appointment will be terminable by three months' notice on either side.

Applications, stating age, experience and qualifications, accompanied by copies of not more than three recent testimonials and endorsed "Obstetric Medical Officer and Deputy Superintendent," should be sent to the undersigned not later than Tuesday, February 1st.

Forms of application can be obtained from the Medical Officer of Health, Public Health Department, Town Hall, Rotherham.

Municipal Offices, CHAS. L. des FORGES, Rotherham. Town Clerk.
January 11th, 1938.

CITY OF SHEFFIELD. CITY GENERAL HOSPITAL.

ASSISTANT MEDICAL OFFICER.

Applications are invited from duly qualified medical men for the appointment of ASSISTANT MEDICAL OFFICER (Grade II) in the above hospital. There are two vacancies.

Candidates should have previous hospital experience and, in addition, for one appointment should have special experience in obstetrics.

For the other appointment special experience in surgery is required.

Salary, £350, rising by £25 to £450 per annum, with the usual residential allowances. The medical officers may be required for a time to live outside the hospital, and for this an allowance for subsistence will be paid.

These appointments are designated under the Local Government and Other Officers' Superannuation Act, 1922.

Applications, stating age, qualifications and experience, together with copies of three recent testimonials, should be sent to THE MEDICAL SUPERINTENDENT, City General Hospital, Sheffield, S.1, on or before January 25th, 1938.

GLOUCESTERSHIRE JOINT BOARD FOR TUBERCULOSIS.

Standish House Sanatorium, Stonehouse, Glos.

Applications are invited from registered medical men for the post of JUNIOR ASSISTANT MEDICAL OFFICER at the above institution. No previous professional experience is necessary.

There are at present 250 beds, including men, women and children. There is an orthopaedic block. The salary is £250 per annum, with board, furnished apartments and laundry in addition.

The appointment is for six months (with the possibility of extension for a further period of six months) and may be terminated within that period by one month's notice on either side.

Applications, stating qualifications and age, and accompanied by copies of three recent testimonials, should be received not later than January 26th.

Shire Hall, RICHARD L. MOON, Gloucester. Clerk of the Joint Board.
January 10th, 1938.

KENT COUNTY OPHTHALMIC AND AURAL HOSPITAL, MAIDSTONE.

(109 Beds)

Applications are invited for the post of OPHTHALMIC HOUSE SURGEON, which post is now vacant on February 1st, 1938. The appointment is for six months, but a senior post at a higher salary may be given after that period if mutually agreed upon. Candidates must be duly qualified and registered Medical Practitioners, qualified and of British birth and nationality, and single, and of proved experience of refractions. Salary at the rate of £200 per annum, with board, residence and laundry. The Hospital is recognized by the Examining Board for the D.O.M.S.

Applications, stating age and qualifications, together with copies of not more than three testimonials, should be sent to the undersigned.

JOHN W. STRICKLAND, Secretary.

LANCASHIRE COUNTY COUNCIL. PUBLIC ASSISTANCE COMMITTEE.

WHISTON COUNTY HOSPITAL, NEAR PRESCOT.

RESIDENT MEDICAL OFFICER.

Applications are invited from Registered Medical Practitioners for the appointment of Resident Medical Officer at the above Institution (500 Beds). Candidates must be unmarried.

Preference will be given to candidates having previous hospital experience, particularly in Midwifery. Feelees are available for candidates desirous of qualifying for the D.C.O.G.

Salary at the rate of £350 per annum, together with the usual residential emoluments.

The appointment will, in the first instance, be for a period of six months, the successful applicant being eligible for reappointment for a further period of six months at the end of that period.

Forms of application may be obtained from the County Medical Officer of Health, Public Assistance (Hospital and Medical) Department, County Offices, Preston, to whom all applications, accompanied by copies of not more than two recent testimonials must be forwarded so as to be received not later than Thursday, January 25th, 1938.

GEORGE LITHERTON,

Clerk of the County Council.

County Offices, Preston.
January 4th, 1938.

ANCOATS HOSPITAL, MANCHESTER.

CASUALTY OFFICER (lady or gentleman). Twelve months' appointment. Salary £250 per annum, with luncheon and tea provided. Applicants who have passed the Primary Fellowship Examination of one of the Royal Colleges of Surgeons will be preferred. The successful applicant will work for the Resident Surgical Officer on alternate week-ends and other scheduled times.

Applications, stating age, experience and qualifications, to be forwarded to the undersigned on or before January 26th, together with copies of three recent testimonials.

By Order of the Board,
HERBERT J. DAFORNE,
General Superintendent and Secretary.

ANCOATS HOSPITAL, MANCHESTER.

ASSISTANT PATHOLOGIST, lady or gentleman, whole-time appointment, no private work allowed. Salary £400 per annum, live out, luncheon and tea provided. The appointment is for twelve months and is renewable. During the first six months a certain amount of research work will be conducted.

RADIOLOGICAL OFFICER, lady or gentleman, whole-time appointment, non-resident, no private work allowed. Salary £400 per annum with luncheon and tea. The appointment is for twelve months and is renewable. Candidates must hold the D.M.R. diploma.

Applications for the above posts, stating age and particulars of qualifications and experience, to be forwarded to the undersigned on or before January 19th, 1938, together with copies of three recent testimonials.

By Order of the Board,
HERBERT J. DAFORNE,
General Superintendent and Secretary.

BOOTLE GENERAL HOSPITAL, BOOTLE, LIVERPOOL, 20 (103 Beds).

ONE HOUSE PHYSICIAN

TWO HOUSE SURGEONS

ONE CASUALTY OFFICER

Applications are invited for the above posts, tenable for 6 months from April 1st, 1938. The salary attached to each post is £150 per annum with board, residence and laundry.

Applicants must be duly qualified and registered under the Medical Act.

Applications, with copies of testimonials, should reach me as soon as possible.

A. COOPER,
Secretary-Superintendent.

GRIMSBY AND DISTRICT HOSPITAL (164 Beds)

Applications are invited for the post of SENIOR HOUSE SURGEON (100 Beds) and JUNIOR HOUSE SURGEON (100 Beds). Remuneration at the rate of £12 and £10 per annum respectively, with board and laundry.

Candidates must be fully qualified and registered, and previous hospital appointment experience is desirable. Dates for interview February 1st, 1938. The successful candidates will be appointed for six months and may apply for re-election.

Applications, stating age, qualifications, experience, and not more than three recent testimonials, to be forwarded to the undersigned immediately.

January 4th, 1938. Secretary-Superintendent.

BOROUGH OF EALING.**ASSISTANT MEDICAL OFFICER OF HEALTH
RESIDENT ASSISTANT MEDICAL OFFICER**

Applications are invited for the above appointments from duly qualified medical men with a Public Health qualification.

Assistant Medical Officer (Man).—A candidate must have had at least three years' experience in the practice of his profession. The person appointed will be required to carry out medical inspection of school children and child welfare work and perform such other duties as may be allotted as Assistant to the Medical Officer of Health and School Medical Officer.

He will be required to devote his whole time to the duties and will not be allowed to engage in private practice. The salary will be at the rate of £600 per annum, rising by £25 per annum to £700.

Resident Assistant Medical Officer. (Man)—Single.—A candidate must have had experience in the treatment of cases of infectious disease at an Isolation Hospital. The duties will include the medical care of patients in the Chiswick and Ealing Isolation Hospital, South Ealing, and the medical inspection and treatment of school children at schools and health centres in the borough of Ealing. The person appointed will reside at the Isolation Hospital where furnished rooms and board will be provided.

He will be required to devote his whole time to the duties and will not be allowed to engage in private practice. The salary will be at the rate of £350 per annum, rising by £25 per annum to a maximum of £550, plus board and residence as indicated above and valued at £150 per annum.

A deduction of 5 per cent. will be made from the salary in each case in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, which has been adopted by the Council and the appointment will be subject to passing the Council's medical examination in connection therewith. Canvassing will be a disqualification.

Copies of the application forms and terms of appointments can be obtained from Dr. Thomas Orr, Medical Officer of Health, Town Hall, Ealing, W.5, to whom applications accompanied by copies of not more than three recent testimonials must be delivered not later than January 20th.

R. H. WANKLYN

Town Hall, Ealing W 5 Town Clerk

BOROUGH OF EALING.**OPHTHALMIC SURGEON**

Applications are invited from registered medical practitioners of recognised consultant and specialist status in ophthalmology for the position of Ophthalmic Surgeon in connection with the Council's Health Centres. The successful applicant will be required to attend on three sessions a week during 40 school weeks, or 120 sessions in the year, for the purpose of examining and advising patients referred to him by the medical staff of the School Medical and Maternity and Child Welfare Services. The remuneration will be £275 per annum. Canvassing will be a disqualification.

Forms of application and copies of terms of appointment may be obtained from Dr. Thomas Orr, Medical Officer of Health, Town Hall, Ealing, W.5, to whom applications, accompanied by three recent testimonials and endorsed "Appointment of Ophthalmic Surgeon," must be delivered not later than January 20th.

R. H. WANKLYN,

Town Hall, Ealing, W.5 Town Clerk.

COUNTY OF EAST SUFFOLK.**JOINT APPOINTMENT OF MEDICAL OFFICER
OF HEALTH FOR WOODBRIDGE URBAN
DISTRICT, MEDICAL OFFICER OF HEALTH
FOR DEBEN RURAL DISTRICT AND
ASSISTANT COUNTY MEDICAL OFFICER.**

Applications are invited from male registered Medical Practitioners holding the Diploma of Public Health for the combined post of Medical Officer of Health for the Woodbridge Urban and the Deben Rural Districts and Assistant County Medical Officer. The duties as Assistant County Medical Officer will include public health work, school medical inspection, and maternity and child welfare and tuberculosis work. The person appointed will be required to devote the whole of his time to the service of the three Councils.

The total commencing salary will be £776 per annum on the basis of a decision by the Advisory Committee set up under Section X of the Askwith Memorandum. Motor-car allowance will be paid according to the County Council's scale for the use of the Officer's car.

The person appointed will be required to pass a medical examination and to contribute to the Council's Superannuation Fund.

Applications must be made upon a form to be obtained, together with further particulars, from the County Medical Officer of Health, County Hall, Ipswich, to whom the completed forms should be returned not later than Saturday, January 20th.

C. C. CLARK, Clerk of the County Council.
Ipswich, January 15th, 1938.

METROPOLITAN BOROUGH OF ISLINGTON.**Appointment of ASSISTANT MEDICAL
OFFICER.**

The Council invite applications from members of either sex whose age must not exceed 40 years for the appointment of an Assistant Medical Officer, whose duties will consist mainly of maternity and child welfare work, to be carried out under the direction of the Medical Officer of Health. The duties will include certain administrative work in the wards of two voluntary Welfare Centres, clinical work at the Council's Day Nurse, artificial sunlight treatment, diphtheria immunisation clinics, and such other duties in connection with maternity and child welfare and public health as may be required by the Council.

Candidates must be registered medical practitioners, with the Diploma of Public Health or Degree of Sanitary Science. They must also possess special children's and infants' experience and knowledge of the treatment of nutritional disorders of infancy, and previous experience of maternity and child welfare work, ultra-violet light therapy and diphtheria immunisation.

The salary for the appointment will be at the rate of £600 per annum, rising by annual increments of £25 to £750 per annum. The candidate appointed will be required to devote whole time to the duties of the office, and will not be allowed to practise privately. The appointment will also be subject to the rules and regulations of the Council from time to time in force relating to their officers.

Applications, accompanied by copies of not more than three recent testimonials, on forms to be obtained from the undersigned, must be delivered at the address stated below not later than Wednesday, January 26th, 1938, endorsed "Appointment of Assistant Medical Officer."

Canvassing, directly or indirectly, will disqualify. W. ERIC ADAMS, Town Hall, Upper Street, N.1. Town Clerk.
December 30th, 1937.

CITY OF LEEDS.**ASSISTANT MEDICAL OFFICER**

Applications are invited from qualified and registered medical practitioners for the post of Assistant Medical Officer for Maternity and Child Welfare. Applicants must have had not less than three years' postgraduate experience, including experience in General Medicine and Surgery, and special experience in Obstetrics and Ante-Natal work, and in the treatment of Children's Diseases and Disease of Women. Preference will be given to candidates possessing the D.P.H.

Under the present Grading Scheme of the Council, the commencing salary for the post is £500 per annum and the maximum salary £700, with annual increments of £25, subject to satisfactory service, and the first increment will take effect on April 1st following the completion of twelve months' service.

The person appointed will be required to pass a medical examination, and to contribute to the Superannuation Fund established under the Local Government and Other Officers' Superannuation Act, 1922. The appointment will be terminable by one month's notice on either side.

Form of application and particulars as to the duties of the appointment may be obtained from the undersigned.

APPOINTMENTS.—Contd.

THE HOSPITAL FOR SICK CHILDREN,
Great Ormond Street, London, W.C.1.

Applications are invited for the post of ASSISTANT PATHOLOGIST (male).

Candidates, who must possess a legal qualification to practise, are required to send in their applications, addressed to the Secretary, accompanied by copies of not more than three testimonials, given specially for the purpose, before 12 o'clock on Monday, January 31st, 1938.

The appointment is made for one year, and is non-resident.

Salary £400 per annum, with facilities for Private Pathological Practice.

The selected Candidate will be required to take up his duties not later than February 16th, 1938, preferably earlier.

All Candidates must be in attendance to appear before the Joint Committee on Wednesday, February 2nd, 1938, at 4.45 p.m.

Forms of application, copy of the rules, and details of the appointment will be supplied on application to the undersigned.

HERBERT F. RUTHERFORD,
Secretary.

December, 1937.

THE HOSPITAL FOR SICK CHILDREN,
Great Ormond Street, London, W.C.1.

There are vacancies for two ANAESTHETISTS. Candidates must be registered medical practitioners and be prepared to take up their duties at an early date.

The appointment is for one year, but is renewable and carries with it an honorarium of £15 15s. per annum, and an allowance of £6 6s. to provide a substitute during annual leave.

Candidates are invited to send in their applications, addressed to the Secretary, with copies of not more than three testimonials written specially for the purpose, before 12 o'clock on Monday, January 31st, 1938, and must appear personally before the Joint Committee at their Meeting on Wednesday, February 2nd, 1938, at 4.45 p.m.

Forms of application and copies of the rules are obtainable from the undersigned.

HERBERT F. RUTHERFORD,
Secretary.

January, 1938.

THE MIDDLESEX HOSPITAL, W.1.

DEPARTMENT OF PSYCHOLOGICAL
MEDICINE.

A vacancy is hereby declared for an HONORARY PHYSICIAN in charge of the Department of Psychological Medicine. Candidates must be Fellows or Members of the Royal College of Physicians of London, and should be both psychiatrists and have had experience of the modern treatment of Psycho-neuroses.

Applications (30 copies) must be submitted to the undersigned by February 12th, 1938.

By Order of the Board.

S. R. C. PLIMSOLL,
Secretary-Superintendent.

NATIONAL HOSPITAL, QUEEN SQUARE,
W.C.1.

HOUSE SURGEON.

Applications are invited for the post of House Surgeon. The work is concerned almost entirely with the surgery of the central nervous system, and it is desirable that candidates should have had previous experience of general surgery. Applications, accompanied by three recent testimonials, should be sent to the undersigned not later than Monday, January 24th. The salary is £100 per annum, with board and lodging.

GODFREY H. HAMILTON,
Secretary.

THE HOSPITAL FOR SICK CHILDREN,
Newcastle-upon-Tyne.

Applications are invited for the posts of: HOUSE PHYSICIAN and HOUSE SURGEONS (male or female) for six months as from February 1st, 1938. Salary at the rate of £100 per annum, together with board, residence and laundry.

Applications, stating age and qualifications, together with copies of testimonials, to be sent to the Secretary, Mr. NEIL BROOME, 18, City Road, Newcastle-upon-Tyne, 1 on or before January 21st, 1938.

TAUNTON AND SOMERSET HOSPITAL,
TAUNTON.

HOUSE SURGEON (male) required end of January. Salary, rate of £125 p.a., board, residence and laundry, and retention of certain fees.

Applications, with copies of not more than three recent testimonials; to F. J. I. Stacey, Secretary.

ROYAL VICTORIA INFIRMARY,
Newcastle-upon-Tyne.

The House Committee by Resolution declare vacant the office of HONORARY SURGEON.

According to statutory provision every candidate must be a registered Graduate in Surgery of any University recognized by the General Council of Medical Education and Registration of the United Kingdom, or a Registered Fellow, Member, or Licentiate of one of the Royal Colleges of Surgeons of the United Kingdom, provided that he is practising as a Surgeon and not as a General Practitioner.

Applications must be sent to the House Governor and Secretary, Royal Victoria Infirmary, Newcastle-upon-Tyne, not later than Thursday, January 27th, 1938. The appointment will be made on February 3rd, 1938.

Personal canvassing will be considered a disqualification for office.

S. DUNSTAN,

January 10th, 1938. House Governor and Secretary.

ROYAL HALIFAX INFIRMARY,
(250 Beds.)

RADIOLOGIST.

Applications are invited for the above appointment from fully qualified registered Medical Practitioners who have had experience in diagnostic and therapeutic radiology, and who possess a recognized Diploma in Radiology.

The salary will be £700 per annum, and a private practice is to be purchased. Particulars and conditions can be obtained from the undersigned.

Applications, stating age, qualifications and experience, accompanied by the originals of not more than three recent testimonials, must be received by the undersigned not later than Thursday, January 20th, 1938. Special application forms are not required.

A. MIDDLETON,

January 10th, 1938. Secretary.

SWINDON AND NORTH WILTS VICTORIA
HOSPITAL.

Applications are invited for the post of HOUSE SURGEON, male, British or Irish, unmarried. Salary £125 per annum, with board, residence and laundry.

Appointment is for six months in the first instance. There are two residents. The hospital is fully equipped for general work and the specialties. Private beds; no obstetrics. The post is suitable for a recently qualified man, and there is time for reading. Applicants must be registered under the Medical Act.

Applications, stating age and qualifications, with copies of three recent testimonials, to reach the undersigned by January 25th.

KENNETH N. KNAPP,
Secretary.

THE GLOUCESTERSHIRE ROYAL
INFIRMARY AND EYE INSTITUTION,
GLOUCESTER. (225 Beds—Five Residents.)

Applications are invited for the post of RESIDENT SURGICAL OFFICER (male), salary at the rate of £200 per annum, with board, residence and laundry. Candidates must be fully qualified and unmarried and have held previous house appointments. The appointment is for twelve months, which may be extended.

Applications, stating age, qualifications and nationality, together with not less than three recent testimonials, should be received by the undersigned not later than Wednesday, January 26th.

The elected candidate will be required to enter upon his duties on Thursday, February 3rd next.

F. J. SYMONS,

January 6th, 1938. Secretary.

ST. ANNE'S HOME, ALTRINCHAM,
Cheshire.

Southwark, S.E.

Applications are invited for the post of **HOUSE PHYSICIAN (male)** for six months from February-12th, 1938 (first two months in the Casualty Department). Salary at the rate of £120 per annum, with board and residence.

Applications, with copies of three recent testimonials, should be sent to the undersigned, from whom particulars can be obtained, not later than first post on January 19th.

W. H. SIDNELL,
House Governor.

INGHAM INFIRMARY, SOUTH SHIELDS.

Wanted, **JUNIOR HOUSE SURGEON (male)**. Salary £150 per annum with board, residence and laundry. No out-visiting. Candidates must hold registered qualifications in medicine and surgery. The appointment will be terminable by one month's notice. Applications, stating age and accompanied by copies (which will not be returned) of recent testimonials, to be sent to the undersigned, from whom further particulars may be obtained.

JOHN POTTER,
Secretary.

KING'S COLLEGE HOSPITAL.

The Committee of Management invite applications for the post of **ASSISTANT PHYSICIAN**. Applications, with copies of three testimonials, should be sent before February 8th, 1938, to the House Governor, King's College Hospital, Denmark Hill, S.E.5, from whom particulars of the duties may be obtained. Candidates must be Members or Fellows of the Royal College of Physicians of London.

LONDON HOSPITAL, E.1

Applications are invited for the post of **SURGICAL FIRST ASSISTANT AND REGISTRAR**. Candidates must be Fellows of the Royal College of Surgeons. The appointment is for one year, but is renewable annually, on application, for two further periods of one year. Salary £330 per annum payable by the Hospital and Medical College jointly. Applications should arrive at the Hospital not later than by the first post on Saturday, February 12th.

ARTHUR G. ELLIOTT,
House Governor.

METROPOLITAN HOSPITAL,
London, E.8.

Applications (male) are invited to fill a vacancy on the **HONORARY ANAESTHETISTS STAFF**. The duties will be to attend the hospital each Wednesday morning for an Ear, Nose and Throat Session. There is an honorarium of £25 per annum attached to the post.

Applicants should apply to the undersigned by January 19th next, giving such evidence of their fitness for the post as they care to submit.

FRANK JENNINGS,
House Governor and Secretary.

POPLAR HOSPITAL FOR ACCIDENTS
East India Dock Road, Poplar, E.14.

The Committee invites applications for the appointment of **SECOND RESIDENT OFFICER (male)** at a salary at the rate of £175 per annum, all found. Candidates must have held appointments as House Surgeon at a Hospital.

Applications must be accompanied by a statement of the candidate's qualifications and forwarded to the Secretary, with three recent testimonials, not later than Tuesday, January 18th, 1938. The appointment is for a period of six months.

ROYAL MASONIC HOSPITAL,
Ravenscourt Park, W.6.

A post of **RESIDENT SURGICAL OFFICER (male)**, one of three Residents, will be vacant on March 1st, 1938. Salary at the rate of £250 per annum, with board, residence and laundry. The appointment is for six months. Candidates must be registered, and must have held recent appointments at a general hospital. The Institution (145 beds at present, but to be increased) is primarily for paying patients of both sexes of moderate means usually unable to afford ordinary Nursing Home treatment, etc.

Applications, stating full particulars, to be sent on or before 24th inst., to the Honorary Secretaries, from whom further information may be obtained.

ROYAL NATIONAL ORTHOPAEDIC HOSPITAL.

Applications are invited for the posts of **HOUSE SURGEON (Two, male, unmarried)** at this hospital's Country Branch at Brockley Hill, Stanmore, Middlesex. 278 beds (160 cases of surgical tuberculosis).

TAVISTOCK SQUARE

Nearly Sixty years of Standardization

■ ■ ■

PARKE, DAVIS & Co., the first House to practise the standardization of medicinal preparations, were for many years its chief exponents

1879.—Normal Liquid Ergot standardized by Parke, Davis & Company on the amount of precipitate thrown down on adding alcohol.

1882.—Chemical standardization introduced by Parke, Davis & Company. The preparations of Nux Vomica were the first to be assayed in this way.

1895.—Houghton's frog method applied by Parke, Davis & Company to the standardization of digitalis, strophanthus and squill.

1896.—Ergot and its preparations physiologically assayed for the first time in manufacturing pharmacy. The cock's comb test was employed.

1901.—Adrenalin introduced by Parke, Davis & Company; standardized by its effect on the blood-pressure of test animals.

1908.—Pituitrin introduced by Parke, Davis & Company; standardized by its effect on blood-pressure, and later, by its effect on uterine muscle also.

1927.—Two active principles, pitocin, and pitressin (formerly known as oxytocin and vasopressin), separated by Parke, Davis & Company from posterior pituitary extract; the former standardized by the oxytotic test and the latter by the pressor test.

1882-1938.—All alkaloidal drugs issued by the firm have been standardized by percentage of active principle and non-alkaloidal drugs by the percentage of resin or extractive.

'Elastoplast' in the treatment of large and deep-seated Varicose Ulcers

In the case of a large or cavitated ulcer, greater support is afforded to the lesion by the use of Paragon Sponge Rubber in conjunction with the 'Elastoplast' bandage. Two strips of the 'Elastoplast' bandage, 6 in. long are cut and laid one on each side of the leg from the malleolus upwards. Then a piece of the sponge rubber of suitable size is placed over the ulcer, completely surrounding it for several inches, before the 'Elastoplast'

Bandage is applied in the usual manner, from the toes upwards, as tightly as possible. The sponge rubber, besides giving extra support, prevents the bandage from cutting into the ulcer and the surrounding weak tissue, and also promotes quicker healing.

A copy of "Elastoplast Technique," giving particulars of this and many other uses of the 'Elastoplast' bandage, will be sent on request to the address below.

BREAD

in the DIET

The latest medical work on weight-reducing diet has the following significant passage:

"DURING a period of starvation or diminished diet, that is to say, one that is less than the level of the body's requirements, if the oxidation of fat is incomplete, poisonous compounds known as acetone bodies are formed. Their formation is likely to occur unless sufficient carbohydrate food is taken to oxidise the fats and prevent their poisonous action.

"The application of the principle of undernourishment, with the use of carbohydrate foods alone, is an extremely good way of causing a reduction of weight, rapidly and safely."

"Weight Reduction Diet and Dishes," p. 31

BUIE'S PROCTOLOGY A NEW BOOK

Just Issued! This entirely new book by Dr. Louis A. Buie is all that its name implies. It is, indeed, "Practical Proctology"—clear, concise, a record of clinical experience. Furthermore, this book was planned and written with specific consideration for the needs of the General Practitioner as well as those of the Proctologist, Surgeon, Gastro-enterologist and Internist. It is both medical and surgical.

Dr. Buie has given particular attention to those diseases and conditions of most frequent occurrence in practice. There are 63 pages on Haemorrhoids and Rectal Prolapse including the injection treatment for use in surgery or hospital, as well as operative technique. There is a 34-page discussion of Anal Pruritus with the author's own method of treatment that has proved successful in 92 per cent of the cases treated. Chronic Ulcerative Colitis is taken up with full consideration for diagnosis and treatment, including 6 colour illustrations of the progressive stages. It is only necessary to compare the bowel with these pictures in order to make the diagnosis.

Dr. Buie indicates clearly when proctoscopic examination should be undertaken, describes the necessary preliminaries, then gives you the entire technique. The details of pre-operative preparation and post-operative care are precisely given, including the use of the various types of anaesthesia, position of the patient, exposure of the field, etc. Throughout his book, Dr. Buie describes both operative technique and non-operative measures in step-by-step detail and clarifies his statements with many vivid illustrations.

CONTENTS of this NEW BOOK

Attitude of the Physician and of the Patient; Indications for and Technique of Examination

Anatomic Aspects

Preoperative Preparation and Postoperative Care

Cryptitis and Papillitis and Muscular Spasm

Anal Fissure

Anal Fistula

Haemorrhoids and Rectal Prolapse

Anal Pruritus

Tuberculosis of the Anus and Rectum

Chronic Ulcerative Colitis

Amoebic Dysentery, Bacillary Dysentery, Balantidiasis, Actinomycosis

Diverticula of the Colon

Polypoid Disease of the Colon

Malignant Diseases and Fectitious Ulcer

Melanosis Coli

Benign Rectal Stricture

Syphilis, Chancroid, Gonorrhoea and Granuloma

Pilonidal Disease

Dietary Formulas and Prescriptions

By LOUIS A. BUIE, A.B., M.D., F.A.C.S., Head of Section on Proctology, the Mayo Clinic; Professor of Proctology, The Mayo Foundation. Octavo of 512 pages, with 152 illustrations, including 6 in colours. Cloth, 30s. net.

CLINICAL HEART DISEASE

By SAMUEL A. LEVINE, M.D., F.A.C.P., Assistant Professor of Medicine, Harvard Medical School. Octavo of 450 pages. Cloth, 24s. net.

"Dr. Levine has succeeded in casting aside the mantle of obscurantism and by discarding many of the technicalities and dogmatisms which have tended to encumber this subject in recent years, he has made a refreshing and interesting book which will appeal to the practitioner to whom it is expressly addressed. This is a notable achievement, for few specialists in any branch of study are gifted with the ability to write so simply, lucidly and clearly."—EDINBURGH MEDICAL JOURNAL

ENDOCRINOLOGY ^{IN} MODERN PRACTICE

By WILLIAM WOLF, M.D., M.S., Ph.D. Octavo of 1018 pages, with 253 illustrations. Cloth, 42s. net.

"The section on diagnosis is constructed on a practical plan with a suggested order of examination and an interpretation of the value of laboratory findings. We would specially call attention to the chapter on bone development. Not many of us carry in our memories the dates of the appearance of centres of ossification or of epiphyseal junctions. The series of diagrams illustrating such facts form a valuable picture gallery for ready reference."—BRITISH MEDICAL JOURNAL

PRE- AND POST-OPERATIVE TREATMENT

By ROBERT L. MASON, A.B., M.D., F.A.C.S., Assistant in Surgery at the Massachusetts General Hospital. Octavo of 495 pages. Illustrated. Cloth, 25s. net.

"... gathers together a considerable amount of very useful information and presents it in an arresting and interesting manner... it will appeal to the house-surgeon requiring help in a specific case, and will make a useful addition to the library of a surgeon."—EDINBURGH MEDICAL JOURNAL

DISEASES OF THE LARYNX

By CHEVALIER JACKSON, M.D., Sc.D., LL.D., F.A.C.S., and CHEVALIER L. JACKSON, A.B., M.D., M.Sc. (Med.), F.A.C.S., Philadelphia. Octavo of 555 pages, with 221 illustrations, including 11 plates in colour. Cloth, 35s. net.

"... the fullness of the descriptions, the magnificent new coloured plates and other illustrations with which the book is liberally adorned, must excite admiration and satisfaction that Dr. Jackson has collected all that he has to say about the larynx between the covers of a single volume."—BRITISH MEDICAL JOURNAL

Why the filter tip?

In every "du Maurier" cigarette, you will find the filter tip. It is a five-layer protection—three layers of pure white vegetable tissue alternating with two of cellulose fibre. No irritant that might harm a sensitive throat can get through that. No stray "bits" can worry the throat. But there's no stopping the clean flavour of the finest Virginia tobacco.

du MAURIER

the perfect cigarette with the exclusive filter tip

TEN FOR SIXPENCE • TWENTY FOR ONE SHILLING

WOLSELEY 14/56 H.P.

-the Doctors' Car

The price of the 14/56 h.p. Saloon is from £260—the Salon de Ville £325 18/80 h.p. are from £280. Super Sixes from £350, and the 12/45 h.p. from £245.

THE suitability of the Wolseley 14/56 h.p. for the work a doctor has to do is so striking that large numbers of practitioners all over the country have chosen it above all others. A doctor's work calls for:—

EASY STARTING.—In the Wolseley 14/56 h.p. a thermostatically-controlled water system does away with warming up delays and sluggish pulling. A 12-volt electric system and twin batteries ensure ample starting energy.

ROOMINESS.—Quick and easy exit through wide doors, fresh air renewal every 60 seconds and anatomically correct seating mean lack of fatigue on even the longest day.

NIGHTWORK.—Powerful headlamps, twin fog lamps, stop and reversing lamps and duplex screen wipers lessen the strain of dark and rainy nights.

ECONOMY.—24 to 28 miles per gallon is good for a "14" Wolseley stabilised production policy lowers depreciation.

QUIET.—Body, door and floor are completely insulated from noise—the interior from fumes.

APPEARANCE.—The Wolseley 14/56, either as a Saloon or in its Salon de Ville form, is a distinguished, handsome car—very indicative of the standing of its owner.

BETTER BUILT. A BRITISH CAR

S.U.P. 36

In the treatment of Pneumonia

Clinical evidence extending over a period of ten years confirms the value of S.U.P. 36 in the treatment of acute inflammatory conditions. One well-known physician reported recently that an obstinate case of pneumonia running a temperature between 103° and 104° yielded to treatment with S.U.P. 36, the temperature subsiding after one injection and falling to normal on the next day. The patient made an uneventful recovery.

The administration of S.U.P. 36 is recommended also in influenza, broncho-pneumonia, tonsillitis and many other inflammatory conditions in which pyrexia is an outstanding symptom.

MARMITE

(YEAST EXTRACT)

IN PREVENTIVE MEDICINE

Susceptibility to infection is known to be minimised by correct nutrition.

It is particularly important to ensure that ample supplies of the vitamin B complex are taken, as deficiency of these factors is not uncommon, and may be responsible for a considerable amount of preventable illness.

Marmite contains all the vitamins of the B group and has proved of undoubted value in preventive and curative medicine.

For sample and literature apply to:—

THE MARMITE FOOD EXTRACT CO. LTD., Walsingham House, Seething Lane, London, E.C.3.

SPRAY ARGYROL IN COMMON COLD

BRAND SILVER VITELLIN

At this time of year, with frequent exposure to cold and wet, the common cold takes on a more serious aspect. Tonsillitis, pharyngitis and sinusitis are frequent sequelae when "dread Winter spreads his latest glooms."

The prevention of complications is the first aim of the physician. Early treatment with Argyrol Brand Silver Vitellin not only attacks the infection right at its source, but also quickly relieves the acute distress in the respiratory tract.

The Dowling Argyrol pack and the Argyrol spray (20 per cent solution) have become standard therapy throughout the world. Rhinologists, following the Dowling technique, find the tampon saturated with 10-20 per cent. Argyrol solution, the most effective when used as a local detergent and decongestive for the highly inflamed nasal tissues. The new Argyrol Brand Silver Vitellin tablets in small convenient vials are a great convenience in nose and throat practice. They not only insure accuracy, purity and genuineness, but also save

time, because a fresh, potent solution is thus made available at a moment's notice, in the doctor's surgery, in the operating room and at the bedside.

Argyrol is a unique and original compound; no other silver salt is like it chemically.

THROUGHOUT THE SPAN

The problem of treatment in intestinal stasis is definitely settled in the minds of those thousands of physicians who depend on Agarol.

Agarol is a readily miscible emulsion of high-grade mineral oil and agar-agar with phenolphthalein. Free from alcohol, alkali and sugar, it is suitable for use in every condition where an evacuant is indicated and at every age period.

The palatability of Agarol appeals to all. In appropriate doses it is mild enough for infants, yet active enough for the demands of adult age.

Supplied in 4½ oz.,
7½ oz. and 17 oz.
bottles.

The average adult
dose is one table-
spoonful.

Agarol is not adver-
tised to the public.

Serenol is a sedative with action on the centres of the nervous vegetative system, sympathetic and parasympathetic, and on the cortical centres. Recent knowledge has shown the interaction of nervous vegetative system and endocrine system, and on this knowledge *SERENOL* is based. It is thus a biological, not a symptomatic, sedative, and, unlike many other sedatives, has not a direct depressant action on the cortical cerebral centres.

Serenol is indicated in conditions of anxiety and general irritability, insomnia, hyperthyroidism, hyperadrenalism (as in neurocirculatory asthenia, effort syndrome), the so-called nervous palpitations of the heart, etc.

Serenol is given in the following dosage. For mild cases one to two dessertspoonsful on retiring. For more severe cases one dessertspoonful at 10 a.m., one dessertspoonful at 4 p.m. and two dessertspoonsful on retiring.

Serenol, being a biological sedative containing no barbiturate, is not habit forming.

Measles Control with

IMMUNE GLOBULIN (HUMAN)

Lederle

BECAUSE of the frequency of complications, the mortality rate of measles is high—higher than that for whooping cough, diphtheria and scarlet fever.

Complications can be avoided by the use of IMMUNE GLOBULIN (HUMAN) *Lederle*, particularly those of broncho-pneumonia—responsible for about 50% of deaths in the infant age group (6 months to 3 years).

As a modification dose, one injection of 2 cc. is administered to patients in the infant age group from 6 to 8 days after exposure (for children in the same family this is 2 to 4 days after the appearance of rash in the exposing child). This dosage confers an active and lasting immunity in the majority of cases. For passive immunity of several weeks, a first dose of 2 cc. of IMMUNE GLOBULIN (HUMAN) *Lederle* is administered as soon as contact has been recognized; a second dose of 2 cc. four days later.

IMMUNE GLOBULIN (HUMAN) *Lederle* is distributed in 2 cc. vials and 10 cc. vials.

ALASIL

Better Salicylate Therapy

WHATEVER be the season of the year, there is a wide sphere of utility for "Alasil," the improved form of salicylate medication.

"Alasil" is a very definite advance on ordinary compounds of salicylic or acetyl-salicylic acid both in therapeutic efficiency and in freedom from the risk of unpleasant gastro-intestinal sequelae. This high tolerability is due to the fact that "Alasil" is composed of calcium acetyl-salicylate—the least irritating of the salicylate compounds—and "Alocol" (Colloidal Hydroxide of Aluminium), a powerful gastric sedative and antacid.

A careful series of experimental tests has shown that "Alasil" is more completely absorbed than ordinary salicylate compounds and that it is practically free from the risk of liberating free salicylic acid in the stomach.

Wide clinical experience anticipated these findings by demonstrating that "Alasil" can be pushed or prolonged to a much greater extent than ordinary salicylate compounds and that it can be given with safety to children, adults, the aged, and patients with finely-balanced digestive capacities. An analgesic, antipyretic, and sedative of established value.

A supply for clinical trial with full descriptive literature sent free on request.

M269

"ALOCOL"

Colloidal Hydroxide of Aluminium

Rational Antacid Therapy

APART from those cases due to actual organic disease, the treatment of the syndrome of symptoms known as indigestion, generally resolves itself into an attempt to overcome hypersecretion of acid and to soothe the irritated or inflamed gastric mucosa.

That "Alocol" possesses intrinsic qualities which render it particularly valuable as a gastric sedative and antacid is now well established. Its freedom from the constipating effect of bismuth, the laxative action of magnesium salts and the gas-forming properties of sodium bicarbonate are especially noteworthy.

"Alocol" forms with the gastric contents a colloidal jelly which has the power of adsorbing free hydrochloric acid. Its markedly soothing effect on the gastric mucosa promptly relieves pain and discomfort. It does not interfere with the normal process of digestion and is free from the danger of "alkalosis."

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

GONAD STIMULATION THERAPY — IN MENSTRUAL DISORDERS

ANTOSTAB

Supplied in boxes containing ampoules of 100 mouse units, together with ampoules containing 1 c.c. of 0.90% Sodium Chloride Solution as a solvent for Antostab. Single ampoules and boxes of 6 ampoules.

ANTOSTAB is prepared from pregnant mares' serum and contains the follicle-stimulating factor which has a definite effect on the ovaries and in producing endometrial proliferation.

Clinical reports published in the *British Medical Journal*, 1937, November 6th, page 904, show that in cases of amenorrhoea, the menstrual cycle may be re-established by treatment with Antostab and that following treatment the menstrual rhythm continues normally.

PHYSOSTAB

Supplied in boxes containing ampoules of 100 mouse units, together with ampoules containing 1 c.c. of 0.90% Sodium Chloride Solution as a solvent for Physostab. Single ampoules and boxes of 6 ampoules.

PHYSOSTAB is prepared from human pregnancy urine and contains the luteinising hormone.

It is of value during the second half of the menstrual cycle when it stimulates the production of corpora lutea.

Successful results have been obtained with Physostab in the treatment of undescended testicles and of dystrophia adiposogenitalis.

REFERENCES

During the six years since its introduction, Nembutal has been the subject of more than two hundred reports and references in medical literature. This record is important not only as an indication of the profession's interest, but also as evidence of the extensive clinical investigation to which the drug has been subjected.

- Today, its uses and advantages as well as its limitations are well understood, and the practitioner can make use of Nembutal with full confidence in its safety when administered as recommended.
- Used orally, rectally or, in emergencies, intravenously, Nembutal exerts an extremely rapid sedative action from a dosage only about one-half that of most other powerful barbiturates. This small dosage, by lessening the amount of the drug to be eliminated, makes Nembutal, clinically, one of the safest

of the barbiturates. • Safety, rapidity and brevity of action recommend Nembutal for use as a pre-anæsthetic sedative in both major and minor surgery, as well as for the treatment of insomnia, hysteria, sea-sickness, nausea from any cause, eclampsia, delirium tremens, convulsions from strychnine or other poisoning, as a supplement to morphine in controlling the pain of early cancer and in obstetrics. • Nembutal is available in

a wide variety of forms, the most widely employed of which are the 1½-grain and 1½-grain capsules for oral administration. Comprehensive literature, together with a free trial sample of the 1½-grain Nembutal capsules, will be sent upon request.

'PLASTULES' BRAND HÆMATINIC COMPOUND

IMPROVED IRON TONIC

Large doses of iron are no longer necessary for the successful treatment of hypochromic anæmia and debility. Independent investigations have proved that 'Plastules' yield rapid clinical response, equivalent to the results obtained from massive doses of other forms of iron. The average patient requires only three 'Plastules' Plain daily which obviates the unpleasant effects usually associated with massive iron feedings. Prescribe 'Plastules' for your patients and note the immediate results—appetite and colour return rapidly. Samples and literature on request.

After Influenza Pneumonia and other Acute Infections

The general action of 'Bynin' Amara is manifested by increased tone of the nervous, muscular and cardiovascular systems. It stimulates the digestive organs, improves the flagging appetite, corrects anæmia and aids nutrition generally.

The marked asthenia and nervous depression which are prominent features of the post-influenzal state, yield rapidly to its influence. A course whenever there is any indication of lowered resistance is a valuable safeguard against infection.

In bottles at 2/-, 3/6, 6/6 and 12/-

RICKETS, TUBERCULOSIS AND MALNUTRITION

Cod-Liver Oil has been described by medical writers as the most reliable weapon in the treatment of rickets,¹ and is one of the greatest single nutritional factors in preventive medicine.² Its special value in tuberculosis is well known.

'Allenburys' 'Perfected' Cod-Liver Oil is specially prepared and is selected for its richness in vitamins A and D, as well as for its palatability and purity. It contains not less than 800 international units of the nutrition-promoting vitamin A and 150 international units of the calcifying (antirachitic) vitamin D per gm.

Gastritis

Sanatogen is a *chemical combination* of ninety-five per cent. concentrated milk casein and five per cent. sodium glycerophosphate, which can be easily digested and absorbed even in cases of enteritis. Moreover, it stimulates a better utilisation of whatever ordinary food can be taken.

"I had a female patient age 43 who was always rather below weight and nervy. She suffered severely from acute Gastritis following mild food poisoning and progressed slowly. She was put on carefully chosen soft foods, rest in bed, sedatives and Sanatogen, commencing with one teaspoonful three times daily. The last dose was taken half an hour before settling down for the night. She certainly improved. The stomach could receive and retain, with comfort, more food, and the nervous symptoms showed marked improvement, especially regarding sleep and general interest in life."—L.R.C.P. & S.

Many superstitions and domestic traditions have gathered round this physiological function [menstruation] . . . [but] many time-honoured customs have been abandoned in favour of commonsense habits

RECREATION AND PHYSICAL FITNESS
FOR GIRLS AND WOMEN, PUBLISHED BY
THE BOARD OF EDUCATION

Can we assess the progress that has been made in women's attitude to menstruation? The 'Keep Fit' movement affords a rough index. The enthusiasm with which women are taking part in it seems to indicate that the majority has overcome the difficulties once associated with menstruation.

In this advance the makers of Lilia towels feel they have played some small part. The introduction of a surgically hygienic *soluble* towel solved the twin problems of local discomfort and disposal. Again, the Company's educational work has consistently aimed (to quote

further from the Board of Education publication) to make it 'clearly understood that menstruation is a natural function and not an illness.'

But there still remains that superstitious and periodically ailing minority. The makers of Lilia have published booklets which have been proved successful in educating even these difficult cases. They would consider it a privilege to send to any practitioner samples of their products and specimens of the booklets, exercise and diet charts on which their educational publicity is based.

DIET IN GENERAL PRACTICE*

WITH SPECIAL REFERENCE TO THE AMOUNT OF FOOD GIVEN

BY

LESLIE COLE, M.D., F.R.C.P.

Physician to Addenbrooke's Hospital, Cambridge

The results of treatment by diet are often very different from those aimed at. Sometimes this is because the main idea has been obscured in a mass of comparatively unimportant detail, but more often it is because alteration in one direction has led to deficiency in another. Such errors cannot be avoided unless the constituents of a normal diet are constantly kept in mind, and for this reason these will first be briefly given.

The Normal Diet and its Constituents

For a diet to be normal it must contain enough food. Perhaps it is because this is so obvious that it is so often forgotten. The actual amount required by different people varies much more than books on physiology lead one to suppose. The diet for an "average man" approved by a committee of the Royal Society consists of 100 grammes of protein, 100 grammes of fat, and 500 grammes of carbohydrate. This has a total energy value of 3,400 calories. Many people can maintain health on a much smaller allowance of food or of protein than this, and the tolerance and requirement of fat also vary greatly. The amount of carbohydrate varies very widely, too, but it should always be enough to ensure normal metabolism of fat, and for this the ratio of carbohydrate to fat should not fall below that indicated by Woodyatt's formula, $F = 2C + \frac{1}{2}P$. Finally, in considering quantity it must be remembered that excess may be as harmful as lack.

The importance of vitamins seemed at one time to be overstressed. Recent work, however, by Harris (1935, 1936), Archer and Graham (1936), and others has shown that minor degrees of vitamin deficiency are all too common, and that they often occur in patients on special diets in which the normal vitamin requirement has been overlooked. Diets given in gastric cases are extremely liable to be deficient in vitamin C, and low-residue diets in vitamin B, unless this particular danger is realized and the deficiency corrected. In all diets, therefore, the possibility of such deficiency must be considered.

Every diet must contain certain inorganic constituents, and of these iron, iodine, calcium, and sodium are the ones of which a deficiency may occur. When it does it may result from failure of absorption or excessive loss rather than from actual deficiency in the diet. Witts and others have shown how rapidly many forms of anaemia respond to large doses of iron, but that such response only occurs when the amounts given are far and above those taken

normally. Lastly, every normal diet should contain sufficient roughage, hard food to develop the jaws and keep the teeth healthy, and water.

Deficiency through Dieting

Restriction of diet in one direction may lead to deficiency in another, and the most common of these untoward effects is the result of reducing the food to an amount below the optimum necessary for health. In some cases the reduction is so severe that actual weakness from lack of food occurs. This may happen with diets given for various conditions. In the artificial feeding of infants with diluted milk it is very easy to bring the caloric value too low without realizing it, unless calculations are made to check this. The following is an example of such a mistake.

A premature infant weighing six pounds failed to put on weight. She had been given six feeds in the day, each feed amounting to three ounces, consisting of one part milk and two parts water and half a drachm of sugar: half a drachm of cod-liver oil emulsion was also given daily.

For rough-and-ready reckoning it should be remembered that the child of 6 months or under requires approximately 50 calories per pound, and that one ounce of cow's milk or human milk produces 20 calories, one drachm of sugar 15 calories, and one drachm of fat 30 calories. In this case the calorie requirements were 300. The child was actually getting six ounces of milk, 120 calories: three drachms of sugar, 45 calories: and half a drachm of fat, 15 calories: total, 180 calories, or about 120 short of the theoretical requirement. The replacement of water by another ounce of milk per feed, bringing the total calories up to 300, rapidly produced a normal gain in weight. Minor deficiencies through too great dilution of milk are not uncommon, but they can easily be avoided if such a method of calculation is used. When breast-fed children fail to thrive the cause is often too little milk. In such cases the importance of test feeding to find out exactly how much food is being given cannot be over-emphasized.

Diets for gastric and duodenal ulcer cases afford another example of quantity deficiency, particularly those given in the early stages, consisting mainly of milk. In order to maintain strength and weight and promote healing it may be well to give 2,000 or more calories a day. One pint of milk produces approximately 400 calories, so that five pints will be necessary if the diet consists entirely of milk. This diet is difficult and trying for the patient, and so far as the ulcer is concerned there is no reason why more concentrated fluid feeds, variously flavoured and thickened,

* A lecture delivered to the Isle of Ely Division of the British Medical Association at March on October 22, 1937.

TRADITIONAL LONDON

THE TEMPLE BAR END
OF OLD FLEET STREET

FLEET STREET, known in the 13th century as Fleetbridge Street, is one of the most interesting and most ancient of all the City of London thoroughfares. Famous in past days for its taverns and printing houses, its goldsmiths and bankers, it is now the headquarters of journalism. Temple Bar the most interesting of all London gates and bars, first built in the 14th century, was removed in 1878.

London Hospital Catgut has no less finer traditions behind its development to a leading place in the esteem of Surgeons the world over. It is a product of scientific research, made throughout at the London Hospital under licence of the Ministry of Health.

LONDON HOSPITAL CATGUT

OBTAINABLE FROM ALL LEADING SURGICAL EQUIPMENT HOUSES

consumption was definitely greater in the obese during exercise, and was more than could be accounted for by the greater work associated with the extra weight or higher respiratory rates. The resting pulse rate tended to be higher in the obese.

If obesity produces these effects in patients whose hearts are healthy its effect on those with a weak or damaged myocardium becomes clearer. The opinions of many distinguished physicians might be quoted in support of the view that obesity tends to shorten life. Rolleston (1932) says: "The long-lived are usually spare and seldom fat, having been thin since middle age." It is also supported by life insurance figures. MacLaren (1929) says that cerebral apoplexy, Bright's disease, nephritis, cardiac disease of uncertain nature, and diabetes mellitus all give a much higher mortality in those over weight. It is supported as well by the biologist. Robertson and Ray (1920) have shown, in white mice, that those with relative paucity of tissue accretion in late life tend to be long-lived. From the evidence there is little doubt that in many the tendency to put on weight is a degenerative change. This is a particularly important point, because in numerous cases it can be prevented.

The Causes of Obesity

Before considering treatment of obesity, however, it is essential to discuss its causes. Du Bois (1927) has divided cases into two main groups; endogenous or constitutional, in which there is frank endocrine abnormality; and exogenous, in which no such cause can be recognized. These groups merge into each other, and while the extremes can be recognized there are a large number of cases in which it is impossible to say how far the exogenous or the endogenous factors predominate. The tendency to put on weight is one of the most variable characteristics in different people; one can eat as much and do as little as he likes and his weight does not vary; another has but to eat an extra potato or omit his daily walk and his weight rises. Such tendencies often run in families, and may be likened to other hereditary metabolic disorders such as diabetes or gout. Whatever may be the primary cause, it is certain that in most people gain or loss depends on supply and demand, the amount of food absorbed and the amount of energy used. The effect of variation of food and exercise differs so much in different people that it is impossible to predict with certainty the result of a particular regime in a particular patient, and the effect must be determined by trial and error. In nearly all cases, however, a decrease in the fat-forming elements of the food—carbohydrate and fat—with increased exercise will cause a loss of weight, but the degrees of each required must be found by experiment.

A word must be said here on the use of thyroid gland in obesity. This is valuable when there is hypothyroidism and in some patients who put on weight at the menopause. When, however, there is no thyroid deficiency thyroid extract should only be used as an adjunct to treatment by diet, massage, and graduated exercises, and in most cases it is unnecessary. If these measures fail, then a careful trial of thyroid is advisable. Treatment of obesity with thyroid alone is usually unsuccessful unless the dose is pushed, and then it may be dangerous. Poulton (1931) suggests that many obese subjects, far from possessing a low metabolism, have it slightly raised. To give thyroid in such conditions without reducing weight may mean that still more work is thrown on a heart which has already too much to do. The patient remains fat and feels very ill.

Method of Reducing Weight

Reduction of weight may be said to depend on the application of these principles. Fat formation is prevented by having less fat and carbohydrate in the diet, and metabolism is stimulated by giving protein and increased exercise. Only if these methods fail should artificial stimulation of metabolism by thyroid be resorted to. In actual practice this means that the diet is made up mainly of lean meat, fruit, and green vegetables, with only enough sugar, starch, and fat to prevent feelings of weakness or hunger. In putting patients on such a diet it is wise to begin slowly so that adjustment to the change may be gradual: the degree of change depends on the individual, but once a diet is found that produces a steady fall in weight there is no need to make it more drastic. The scales are the best guide.

The following example shows the method in practice:

A woman, aged 50, with obesity; weight 14 st. 6 lb. There was no evidence of endocrine abnormality. On July 3, 1937, she was put on a diet of lean meat and fruit and green vegetables, with 140 grammes of carbohydrate per day. By July 31 there had been no change in weight, and the carbohydrate was reduced to 80 grammes. On August 14 her weight was 14 st. 5 lb., so the carbohydrate was further reduced to 60 grammes. On October 16 her weight had fallen to 13 st. 4 lb.

Increase in exercise should also be gradual. Graduated exercises, designed where necessary to improve breathing and posture, should if possible be taught and supervised by a qualified masseuse, supervision being relaxed as the patient becomes proficient. It is essential that such exercises should be done regularly at home every day. Other exercises, such as walking for prescribed distances, cycling, or riding, are valuable, and the degree to which these are necessary must be found by trial in each case. The scales and the patient's feelings are again the best guides. In patients with excessive abdominal fat a surgical belt is often a great aid to increased activity.

In ten consecutive patients with uncomplicated obesity treated as out-patients at Addenbrooke's Hospital during the last year for periods ranging from twelve to forty-eight weeks the average loss of weight was 25 lb. each. Reducing diets and graduated exercises were used in all cases, and in only two were small doses of thyroid given in addition.

Occasionally patients do not respond, and these often come from families in which there is a strong familial tendency to obesity. Before beginning treatment careful inquiry into the family history will be of importance as a guide to prognosis.

Effects of Treatment by Weight Reduction

Treatment by weight reduction is often of the greatest value when obesity occurs either as an incidental association or as the result of some other condition, and perhaps unnoticed by the patient at all. Sometimes the actual increase in weight above the normal is comparatively slight and would pass unobserved in a healthy patient. In association with a weak myocardium or a raised blood pressure, however, it becomes profoundly significant, because it may be the one factor which is treatable, and may turn the scales in favour of recovery. Some conditions in which the possibilities of weight reduction should always be considered are: chronic bronchitis, myocardial weakness and degeneration, high blood pressure, visceropituitosis, and fascial rheumatism. In such the methods used are the same as those in simple obesity. Their application is, however, a much more delicate problem. Changes

should not be given. Cream and olive oil, for example, are high-calorie foods of great value. The difference between a diet of, say, 1,000 calories and one of 2,000 may be that between healing and failure to heal; while the lower diet, if continued for long, may make convalescence slower than it need be. Discretion must be used, particularly at the very beginning of treatment, but fuller diets are nearly always well tolerated.

In patients with chronic nephritis and high blood pressure it is not unusual to find that all red meat has been forbidden. If the diet previously has been a very full one and has contained much red meat it is clearly rational to reduce this in order to throw less strain on the kidneys, liver, and heart, but in so doing it must be remembered that to cut off the main source of protein drastically is often to cause a feeling of weakness and depression that is worse and more disabling than the actual symptoms of the disease. Moderate restriction is sound, but the benefit resulting from drastic restriction is at the best nebulous, and is not justified if it produces symptoms. Many patients who have been thus severely treated feel fitter and better in every way when their burdens are lightened. If a patient has been accustomed to take meat three times a day he will probably feel better if he is allowed it once a day rather than not at all.

Diet in Diabetes

In the treatment of glycosuria, whether diabetic or not, excessive dieting is one of many pitfalls. It is very important to make a correct diagnosis before symptoms are masked by what may be excessive, even unnecessary, restriction. Many cases of glycosuria are innocuous and do not need treatment, but are dieted unnecessarily; the symptom has been blindly treated without an investigation of its cause. The following is an extreme example of this mistake.

A man of 40 was sent to the out-patient department suffering from mild hyperthyroidism and chronic pulmonary tuberculosis. Sugar had been found in his urine, and because of this finding his loss of weight had been attributed to diabetes mellitus, and a diet of 100 grammes of carbohydrate, 75 grammes of protein, and 150 grammes of fat given. The glycosuria was actually a symptom of hyperthyroidism, and with his raised metabolism, chronic infection, and restricted diet he was going rapidly downhill. A change to a high-calorie diet with plenty of carbohydrate led to rapid improvement and ultimately complete recovery.

Except in severe cases of diabetes mellitus it is important that investigations of blood sugar and urine should be made before the diet has been altered, so that the correct diagnosis may not be masked by treatment. Once the diagnosis of diabetes mellitus has been made the test of good treatment is whether the patient feels absolutely fit, is able to do full work, and maintains a constant weight. If a normal blood sugar and freedom from glycosuria can also be maintained so much the better; but fitness and efficiency are more important than these, and some of the latter standards may have to be sacrificed. Extreme introspection or neurasthenia is too heavy a price to pay for a normal urine, and in such cases some laxity is preferable. It is desirable, however, that freedom from ketosis should always be maintained.

In diabetics, as in normal people, there is extreme variation in the amount and type of food required, and the best diet for a particular patient must ultimately be found by trial. In patients over 45 the question whether insulin is necessary often arises. In such borderline cases the diet which they can take and still be sugar-free is barely enough

to keep them fit and active. Again decision is by trial and error, but it is a pity to allow patients to struggle on without insulin, under-nourished but sugar-free, when with insulin they could take a fuller diet and feel well. When they develop an infection many such patients will have glycosuria and need insulin; they should therefore be taught how to use it, so that they may take it at once without fuss should occasion suddenly arise. In old people with diabetes it is undesirable to reduce the blood sugar suddenly either by diet or by insulin. Many feel better with a permanently raised blood sugar, and the danger of over-dieting even when glycosuria is present must not be forgotten.

Diet in Other Conditions causing Obesity

In contrast to the diets in which inadvertently too little food is given I would direct attention to those in which the aim is reduction of weight. "Reducing" diets have a wide application, not only for the treatment of obesity as such but in the treatment of other conditions in which a moderate increase in weight often escapes notice. It is of those "other conditions" that I want particularly to speak.

From a theoretical standpoint increase in weight seems likely to lessen physical capabilities in certain directions. The mere addition of a stone means that more work has to be done, throwing extra strain on the circulatory and respiratory systems for which there is no return. To those of sedentary occupation or inclination this may tip the scales on the side of increasing weight and decreasing activity, a vicious circle which, once started, may be difficult to break. The deposit of superfluous fat, particularly around the hip and shoulder girdles and in the abdomen, leads often to degeneration of posture, which predisposes to bad breathing and visceroptosis. Bad breathing, a lax abdominal wall, and diminished activity interfere with the return of blood to the heart. This is normally brought about by muscular movement of the limbs, the descent of the diaphragm during inspiration—which, when the abdominal wall is of good tone, raises the intra-abdominal pressure and drives blood towards the heart—and the negative pressure in the great veins towards the end of inspiration. This effect is shown by the tendency of such patients to develop varicose veins and haemorrhoids. And yet how often does one see varicose veins treated but no attempt made to correct the obesity posture or visceroptosis. Further, the output of the heart is dependent on the venous return, so that the whole circulation is likely to suffer. Increased deposit of fat and diminished activity also has its effects on joints, muscles, fasciae, and tendons, allowing adhesions to form which interfere with the blood supply, so paving the way for chronic rheumatic affections, such as "lumbago," "neuritis," and "sciatica."

Relative Cardiac Insufficiency in Obesity

Proger and Dennig (1932) have made an experimental study of the factors responsible for the so-called relative cardiac insufficiency in obesity. They compared three obese with three normal patients, with the following results.

The vital capacity in the obese was from 12 to 25 per cent. below normal, according to whether height or surface area standards were used. The respiratory minute volume, while the same in both groups at rest, showed an average increase of one-third in the obese during mild exercise. The respiratory rate per minute in the normal and obese during mild exercise was 17 and 18 respectively. The oxygen

Experimental Work

In our original experiments heavy naphtha was found to be lethal to the bed-bug through physical contact. In addition the liquid gives off a vapour which at certain concentrations is also lethal to the bed-bug. It is upon the combined action of these two factors, more especially the latter, that the efficacy of heavy naphtha depends.

The first method of using heavy naphtha consisted in spraying walls, ceilings, and floors, particular attention being given to likely harbourages—for example, behind picture rails, skirting-boards, etc. Masks with a suitable filter are worn by the operators. It was found that certain types of paintwork were damaged by naphtha and that painted linoleum was destroyed, but this has largely been overcome by the use of diffusion screens and covering linoleum with blankets where necessary. Rooms were kept sealed for twenty-four hours, and at the end of this period samples of air were taken for the determination of the naphtha vapour concentration. This was found to be 0.1 per cent. by volume, and showed that the air was only one-third saturated with vapour. Doors and windows were now opened, and ventilation was found to be rapid—so much so that rooms could be entered after a few minutes without any discomfort. After eight hours' airing in this way a further sample of air showed a concentration of vapour of only 0.009 per cent. On closing doors and windows for a further fifteen hours an air sample showed a vapour concentration of 0.009 per cent., thus indicating that concentration does not "build up" by gradual release of absorbed vapour from walls, woodwork, etc.

Effect of Temperature on Vapour Concentration

These experiments were continued throughout the autumn of 1936, but with the first cold weather a number of failures occurred. This experience led to an investigation of the effect of temperature on vapour concentration and a determination of the minimum concentration lethal to the bug. The following table shows the concentration of vapour in air at four different temperatures. The figures will, however, vary slightly with different samples of naphtha.

TABLE I

Temperature (° F.)	Concentration (vol./vol.)
50	0.16%
61	0.21%
70	0.29%
75	0.36%

The minimum concentration lethal to the bed-bug was determined in a series of laboratory experiments in which bugs were exposed for twenty-four hours to various concentrations of vapour. Table II is typical of the results obtained with three different samples of naphtha.

TABLE II

Concentration (vol./vol.)	Sample 1	Sample 2	Sample 3
Per cent.			
0.05	All alive, some rather sick	As for 1	As for 1
0.10	A few survived but died within 48 hours	"	"
0.15	All dead	All dead	All dead
0.20	"	"	"
0.25	"	"	"
0.30	"	"	"

Controls were all alive. The above concentrations apply equally to eggs.

These results, taken in conjunction with those shown in Table I, indicate that for effective disinfection the tem-

perature should not fall below 50° F., though it is not desirable to use heavy naphtha below 60° F. In winter time it will therefore usually be necessary to heat a house to as high a temperature as is practicable, say, 80° F. If an exposed flame is used the heater must be removed before fumigation is started, and smoking or the use of naked lights prohibited while heavy naphtha is being handled. The temperature will inevitably fall, but the rate at which it does so will depend on the outside temperature. It is desirable to heat as long as possible, in order that not only the air but also the walls, etc., shall be warmed.

Loss by Diffusion and Absorption

Unfortunately the concentration figures obtained in the laboratory may not be reproduced in practice. For instance, on fumigating a house in summer at a steady air temperature of 67° F. analysis at the end of twenty-four hours showed a vapour concentration of 0.10 per cent. (or approximately only a third of saturation). There are various physical causes for this—for instance, loss of vapour by diffusion through the fabric of the structure and by absorption in building materials. To counteract these losses blankets were suspended around the walls and sometimes horizontally across the rooms. After the rooms had been sprayed in the usual way these blankets were also sprayed, and analysis of the air after twenty-four hours showed that the vapour concentration was about one-half of saturation. Blankets wetted in this manner formed a reservoir of naphtha ready to vaporize when the concentration dropped below saturation point. While these results were in the right direction they were not entirely satisfactory, and it was found that woollen or shoddy material was not ideal for the purpose. There are exceptions to this. For instance, for maintaining a concentration in a roof space sufficient to kill any bugs which may be there or to prevent them from escaping from lower rooms that have been treated, woollen blankets are laid upon the joists and the whole area is sprayed with naphtha. The slower diffusion from woollen materials is advantageous in a draughty place such as a roof space. Various materials were tried, and finally Egyptian cotton fabrics were chosen. The fabrics had the following characteristics:

	Fabric I	Fabric II
Weight per sq. yd. (oz.)	2	1½
Threads per inch: warp	102	56
weft	99	73

The Use of Diffusion Screens

Naphtha dropped on to the fabric spreads in much the same way as ink spreads on blotting-paper, and when screens are wetted with naphtha and hung near the walls a high concentration of vapour is rapidly produced where it is most needed. Unless treated with a reinforcing dose, which will be described later, the screens are usually dry at the end of a twenty-four-hour fumigation, in marked contrast to the woollen blanket, which always holds a considerable residue of naphtha unevaporized.

The method of suspending these diffusion screens next received attention. Small pin hooks were first tried, but although satisfactory in one way a considerable amount of time was required to fix them. We are indebted to Dr. Macmillan and members of his staff in the health department of the borough of Woolwich for suggesting the use of electric conduit tubing, of half-inch and five-eighths-inch diameter in standardized lengths. This framework is very quickly erected in a room of any size, and by means of distance pieces is kept three inches away from the adjacent walls. The fabric of the diffusion screen is

of diet and exercise must be made more slowly and must be carefully adjusted to the individual case. Before beginning treatment it is best to make a patient describe in detail his diet and daily life. This provides a basis which may be gradually modified on the lines mentioned. In cases of heart disease and high blood pressure it may be best in the early stages to use massage as a prelude to increased activity.

Illustrative Cases

The following are examples showing some types of case to which the above methods are applicable:

Case 1.—A general practitioner, aged 47. The patient gave a history of chronic bronchitis with increasing winter cough for five years; breathlessness on exertion, getting worse for six weeks; and pain over the praecordium on exertion, with fluttering sensations in the chest. Examination in April, 1936, showed the presence of chronic bronchitis and some emphysema. Clinically his heart was found to be enlarged and one inch to the left; there were a tick-tack rhythm and frequent extrasystoles; the resting pulse rate was 90. There was slight cyanosis; the blood pressure was 140/90, and the electrocardiogram normal. His weight was 13 st. 12 lb.; height 5 ft. 7 in. The diagnosis was chronic bronchitis and myocardial weakness. Treatment consisted in gradually reducing the diet and increasing exercise, reducing smoking, and ordering the wearing of an abdominal belt. On May 20 the patient was much better and his weight was reduced to 13 st. 5 lb. On July 7 there were no symptoms; his weight was then 12 st. 2 lb., and he was doing much of his practice on a bicycle. The improvement has since been maintained.

Case 2.—A man aged 62 complained on July 31, 1937, of increasing breathlessness on exertion and slight giddiness of several months' duration. Examination revealed arteriosclerosis, a blood pressure of 190/110, and a pulse rate of 46. An electrocardiogram showed a 3:1 heart-block. His weight was 14 st. 3 lb. After ten days' treatment with massage, mild graduated exercises, and a reducing diet his weight had fallen to 13 st. 4 lb. The symptoms of breathlessness and giddiness had disappeared, and he felt much better.

Case 3.—A woman, aged 52, had had increasing noises in the head and breathlessness on exertion for eight months, with a recent gain in weight. Examination revealed arteriosclerosis and a high blood pressure (200/110). Her weight on July 17, 1937, was 12 st. 8 lb. Treatment consisted in reducing the diet and the prescription of half a grain of thyroid extract each day. After three months her weight had fallen to 10 st. 8 lb., the blood pressure was 200/94, the symptoms had disappeared, and she felt well.

Case 4.—This patient, a woman aged 44, complained of pain in the back on exercise and a "bearing-down feeling" in the stomach. On examination her doctor found sugar in the urine. When seen on June 1, 1937, she was very obese, her weight being 16 st. 9 lb. There was a heavy deposit of fat round the shoulders and hips, and the abdomen was protuberant. The urine gave 2 per cent. of sugar, but no acetone. The resting blood sugar was 2 per cent. Treatment took the form of massage and exercises to reduce weight and improve posture and breathing, with a reducing diet, and an abdominal belt was worn. After three months' treatment the symptoms had gone, the urine was sugar-free, the resting blood sugar 0.12 per cent., and the patient's weight 14 st. 6 lb.

Case 5.—A woman, aged 51, stated that following an attack of influenza in February, 1937, she developed shortness of breath and precordial pain on exertion. These symptoms persisted. When examined on May 19, 1937, her heart was not enlarged, but the quality of the sounds was poor; the blood pressure was 150/80. The abdominal wall was lax, with visceroptosis. Her weight was 10 st. 10 lb. and she was rather fat. Treatment was by means of an abdominal belt, massage, and exercises to reduce weight, and a moderate reducing diet. After five months' treatment her weight was 10 st. 1 lb. She was better in every way and her symptoms had almost gone.

Conclusion

By treatment on the above lines it is often possible to delay the effects of degenerative processes that occur after middle life. To be successful, however, such treatment must be begun early and must be thorough. If it is left too late comparatively little can be done. Both the recognition and the treatment are in the hands of the family doctor, whose opportunities are unrivalled.

COAL-TAR NAPHTHA FOR THE DESTRUCTION OF BED-BUGS*

APPLICATION IN DWELLING-HOUSES AND TENEMENTS

BY

S. A. ASHMORE, B.Sc., A.I.C.

Government Laboratory

AND

A. W. McKENNY HUGHES, D.I.C., F.R.E.S.

British Museum (Natural History)

Attention was first directed to the use of heavy naphtha for the destruction of bed-bugs in a note by us in the *British Medical Journal* (1937, 1, 459) and the *Lancet* (1937, 1, 530). Toxicity experiments with heavy naphtha carried out by Professor G. R. Cameron at the University College Hospital Medical School indicated that danger to man from this substance was not to be apprehended. Extended research employing a wide range of heavy naphthas confirmed the results of the original experiments.

To ensure that only suitable naphthas shall be used the following specification has been drawn up:

Specification for Heavy Coal-tar Naphtha

1. **Colour.**—Shall not be darker than a freshly prepared solution of 1 ml. of N/10 iodine in 1,000 ml. of distilled water.
2. **Specific Gravity.**—Not less than 0.835 and not greater than 0.910.
3. **Water.**—Shall be free from water and other visible impurities at 15.5° C.
4. **Distillation Range.**—Method as defined in B.S.I. Specification No. 479 for coal-tar naphthas. Up to 160° C. not more than 5 ml.; up to 190° C. not less than 90 ml.
5. **Flash-point (Abel).**—Not less than 105° F.
6. **Tar Acids and Tar Bases.**—Not more than 0.25 per cent. of tar acids and 0.25 per cent. of tar bases.

Heavy naphtha complying with this specification may be obtained from all the principal tar distillers throughout the country at prices ranging from 1s. 6d. to 2s. 6d. per gallon, depending partly on the quantity purchased.

* A report to the Bed-bug Infestation Committee of the Medical Research Council.

In our experience the workmen have taken kindly to the use of heavy naphtha and complaints have been few. One man found that the constant use of naphtha had a drying effect upon his skin, but this was soon overcome by the use of lanolin. He has had no further trouble.

Disinfestation of Furniture and Clothing: Van Fumigation

This essential part of the procedure in the eradication of bed-bugs has received considerable attention. Our experiments in this direction are not so advanced as with dwelling-houses, but results obtained when using heavy naphtha indicate that this process can be applied to van fumigation in much the same way as HCN.

We are indebted to Dr. Geffen, M.O.H. Enfield, for his help and the interest he has taken in this aspect of the work.

A small pantechnicon, metal-lined, was fitted with tubular electric heaters placed beneath a duckboard flooring with the terminals outside. Thermostats ensured that a temperature of 100° F. could be maintained. A tent of blankets was made to fit the inside of the van and was sprayed with heavy naphtha, using a foot-operated pump. The doors were sealed with ordinary sealing-paper and the tubular heaters connected up to the electric power point. A temperature of 100° F. is reached in about three-quarters of an hour and a naphtha concentration of approximately 0.5 per cent. is obtained. This concentration is only a quarter of that of the minimum explosive concentration, so that danger from this source is not to be apprehended. Laboratory experiments have shown that an exposure of four hours at this temperature is sufficient to kill the bug, but to provide a good margin of safety a period of seven hours from the time of switching on the current was decided upon.

To simulate the conditions of bug-infested furniture ten calico bags, each containing ten bugs, were secreted in the folds of upholstered chairs, in a mattress rolled up several times, and in various articles of clothing. This load of furniture and clothing was treated with naphtha vapour for seven-hours. At the end of this period the contents of each bag were examined; all the bugs were dead. These experiments were repeated on various occasions, using considerably greater numbers of bugs, and with one exception have been uniformly successful. When bugs were placed in an artificially made air pocket in the middle of a folded feather bed they were not killed.

These experiments open up possibilities of a safe and rapid method of disinfesting furniture in transit. The polish on furniture is not affected by this process, and we are carrying out further investigations as to how soon furniture is sufficiently free from gas to be suitable for return to the tenant. According to indications the period is not a long one, and we do not anticipate any difficulty from the slow desorption of naphtha, not even when bedding is treated by this process.

The Rate of Desorption

An experiment was carried out to test the rate of desorption of naphtha vapour from furniture and bedding disinfested in the van. A typical load of furniture and bedding was kept in naphtha vapour for six hours at 100° F. The van doors were then opened for a few minutes, but no means existed of sweeping the air out of the van. The van was driven to a neighbouring house and the furniture at once unloaded into an upstairs bedroom, the doors and windows of which were kept closed (the fireplace was not sealed). After one hour the room was entered and a sample of air was taken, and a sample was also taken the following morning, at

the end of eighteen hours. The air temperature in the afternoon was 61° F., that of the next morning 55° F. The results of the experiment were as follows:

Concentration of Naphtha Vapour (vol. vol.)	Remarks
After 1 hour : 0.09% Atmosphere unpleasant; irritant action on eyes
After 18 hours : 0.04% Smell of naphtha, but no unpleasant symptoms of any kind

The conditions of this experiment were intentionally not those that would be adopted in routine work. The results clearly show that naphtha vapour is rapidly desorbed from furniture. No "building up" occurred, and had doors and windows been left open, as would be the procedure in ordinary circumstances, the naphtha concentration would soon have been reduced to negligible proportions. It will be advisable to have vans fitted with an extractor fan or shutter which can be opened to allow a current of air to sweep through while the van is being driven along the road. The beating of bedding might also be desirable.

In addition to this experiment two mattresses and pillows were placed in the van at the same time and treated in the same way as the furniture mentioned above. They were then removed to a room and were lain on for an hour. In the first half-hour the windows were closed; the door was also closed, but the fireplace was not sealed. In the second half-hour the windows were open. At first there was slight discomfort to the eyes and nose from the gas being released from the pillows and mattresses, but this quickly passed off. The opening of the windows, however, did not noticeably alter the smell of the mattresses and pillows. It is thought that with some ventilation before the mattresses and pillows are returned to the house there would be no discomfort in sleeping on them the same night. The conditions under which this experiment was carried out were purposely made as adverse as possible.

Heavy naphtha has been used in some twelve hundred houses and tenements, mainly empty, in various parts of the country, and experience has been gained in both summer and winter conditions of fumigation. Houses so treated have been subjected to rigid inspection throughout the year, and in one area the treatment has been successful in ninety-nine houses out of every hundred.

Summary

1. *Method of Applying Heavy Naphtha.*—A method of applying naphtha using light cotton diffusion screens and an automatic delayed-action sprinkler for reinforcing has been developed. Using the new technique the gas concentration at the end of twenty-four hours is 60 per cent. higher than that obtainable by the old method of spraying walls, ceiling, woodwork, etc. With the new method the loss of gas concentration by diffusion is largely overcome, and the gas concentration is at all times above the lethal minimum, when the temperature is 50° F. and over. Failures due to loss of vapour should therefore be eliminated, and it is to be hoped that local authorities using naphtha will adopt the improved process in its entirety. The light tubular scaffolding is quick and easy to erect and affords good support for the diffusion screens. It has the advantage over other methods of suspension that no damage is caused to the structure of the building.

2. *Disinfestation of Furnished Houses.*—This is admittedly a difficult problem, but with the new methods and apparatus further work in this connexion is in hand. The delayed-action sprinkler was not perfected until the past few months, and only one machine has been avail-

usually purchased in strips thirty-six inches wide; these are cut into sixteen-foot lengths and thrown double over the top rail of the scaffolding.

From results of analysis of air samples taken from rooms kept under naphtha vapour it was clear that by using the correct type of diffusion screen a considerably increased concentration of vapour was present at the end of twenty-four hours' fumigation. The degree of saturation at the end of twenty-four hours was increased from 33 per cent. to 80 per cent. by the use of cotton diffusion screens, but it was realized that in the unfavourable conditions presented by a leaky house such a high percentage of saturation might not be maintained at the end of twenty-four hours. The need was felt for a reinforcing dose of naphtha to be put in the room about half-way through the twenty-four-hour period without unsealing. The delayed-action sprinkler has been designed for this purpose. This apparatus automatically delivers a charge of naphtha at a prearranged time varying from eight to eleven hours after the room has been sealed. This is effected by means of an alarm-clock mechanism which at a predetermined time allows naphtha to be thrown on to the diffusion screens from a centrifugal sprayer driven by a clockwork motor.

The concentrations obtained when using the technique as outlined are shown in the table giving the results of an experiment in July, 1937. Three similar rooms were treated with equal quantities of washed heavy naphtha (on the basis of one gallon per 750 cubic feet room space). The procedure was as follows:

Room I: Walls, woodwork, etc., sprayed, but no screens in room (old technique). *Room II:* Walls draped with light cotton diffusion screens, room sprayed, and screens thoroughly wetted. *Room III:* As for Room II; but in addition the delayed-action sprinkler, charged with half a gallon of naphtha, was set to deliver a reinforcing charge eleven hours after the room was sealed. A temperature of 67° F. was maintained throughout.

Table showing Concentration of Naphtha Vapour in the Air of the Rooms at the End of Twenty-four Hours

	Concentration (vol./vol.)	Approx. Degree of Saturation
Room I	0.14 per cent.	50 per cent.
Room II	0.22 " "	80 " "
Room III	0.25 " "	90 " "

Minimum lethal concentration (for twenty-four hours' exposure) = 0.15 per cent.
Saturation concentration at 67° F. 0.27 per cent.

The figures explain themselves, but the following observations are relevant.

(a) The house in which these experiments were carried out was of good construction, and diffusion losses were therefore at a minimum. In an old leaky house the difference in concentration between Room II and Room III would in all probability be much more marked.

(b) The reinforcer enables a second dose of the lighter (or lower-boiling) constituents to be released in the room, and we have reason to believe that these constituents are slightly more toxic to the bed-bug.

Technique for Use of Heavy Naphtha

The technique for using heavy naphtha may thus be summarized as follows:

1. Make a careful examination of the room to be disinfested, for dead spaces. These are frequently boarded in, and in such cases one or more small holes should be drilled to allow easy access of the vapour.
2. Lay wool or shoddy blankets in the roof space on top of the joists and spray these thoroughly with naphtha.

3. Drape walls with light cotton diffusion screens, using the tubular scaffolding as support.

4. Spray walls, woodwork, etc., more especially where there is obvious infestation, and thoroughly wet diffusion screens with naphtha. (Naphtha will remove certain types of paint, and where paintwork is likely to be affected this should not be sprayed.)

5. Set delayed-action sprinkler to deliver a reinforcing charge from nine to eleven hours after the room has been sealed.

6. At the end of twenty-four hours ventilate and remove screens and scaffolding. The screens rapidly dry in the open air, or more quickly in a warm room, and are then available for the next job.

Disinfestation of Furnished Houses

The general practice with regard to furnished and occupied houses varies considerably. In some instances the furniture is removed in a van and treated with cyanide, and the house itself with heavy naphtha, sulphur, or other insecticide. Alternatively the furniture is disinfested in the house by means of some contact insecticide. We have felt for a considerable time that if furniture could be treated effectively *in situ* a great deal of labour and expense would be saved. As with HCN, if heavy naphtha is used alternative accommodation for tenants for one night must be provided. The original experiments in this connexion consisted in the grouping of all the furniture in the middle of the room and covering it over with dust-sheets. The room was then sprayed in the ordinary way. This method has, we understand, been successful in a number of instances, but we are not satisfied that this is the best procedure. The results have not always been satisfactory.

Experiments in two furnished houses have been carried out in Woolwich, and although a few bugs were found afterwards in one room in each house, we consider that the technique, modified as indicated below, will be likely to give satisfactory results. The walls of a furnished room were draped with diffusion screens in the usual way and the furniture grouped together in suitable positions. The delayed-action sprinkler was set down in the middle of a "kiosk" of tubing (as used for erecting the scaffolding around the walls) 3 ft. 6 in. square and 8 ft. high. The four sides of the kiosk were hung with diffusion screens and the floor immediately beneath covered by a blanket. The sprinkler was timed to discharge the naphtha on to the screens ten hours after the rooms had been sealed. The walls and screens were sprayed in the usual way, and the delayed-action sprinkler set to deliver a reinforcing dose as described above.

In these two experiments only one delayed-action sprinkler was available, and in both cases this machine was not used in the rooms where bugs were found subsequently. Having regard to the quantity of absorbent material in a furnished room we consider that a reinforcing dose of naphtha is essential, and it is not unreasonable to assume that if a delayed-action apparatus had been available for each room the results might have been entirely satisfactory. As furnishings and the like absorb the vapour to a large extent we are of the opinion that the initial dose should be increased to, say, 1 gallon to 500 cubic feet of air space. (The method adopted for using heavy naphtha is of the utmost importance, and the training of personnel in its use is also a prime consideration. Adequate supervision should always be given where houses are being treated with heavy naphtha if satisfactory results are to be obtained.)

Although one may not be responsible for the management of many cases of poliomyelitis it is desirable that the results of each examination should be charted, for unless quantitative measurements are made ideas of progress are

When admitted to hospital the distribution of muscular paresis or paralysis in fifty* cases was as follows:

	Per cent.
Both lower limbs; abdominal and spinal muscles	34
Upper limbs; lower limbs; abdominal and spinal muscles	18
Lower limbs only	13
One lower limb	2
Upper limbs	6
One upper limb	6
Both lower limbs and one upper limb	6
One lower limb and one upper limb	2

It will be seen that in more than half the cases the lower limbs and the abdominal and spinal muscles were all affected.

The Muscle Re-education Period

There are few terms more generally misunderstood than "recovery period" in anterior poliomyelitis. Lovett defined it as the period during which spontaneous recovery of muscle function occurs. In most standard English textbooks the term is used without being defined, but the authors do not hesitate to state that its duration is from two to four years. As the discussion which follows usually concerns treatment it is not always clear whether reference is being made to a period of spontaneous recovery—that is, natural recovery without medical care—or the period of improvement under the treatment described. Since most cases are now diagnosed and treated early, the spontaneous "recovery period" is of little importance compared with the period of improvement under muscle re-education. Rather than alter the original definition of recovery period and thereby create confusion I would suggest that the term "muscle re-education period" be used to indicate the time during which the muscles will improve under treatment, assuming that it is started without delay. Although there is no real justification for the idea, many students and practitioners infer that since the "recovery period" is two years it would be useless to suggest muscle re-education for a patient who suffered from the acute disease two or more years ago and who has never been given adequate treatment. In such a case it is always worth while to give at least a few months' treatment, as the following case shows.

A girl of 10 suffered from infantile paralysis when she was 4 years of age. She had never been treated. On examination of the thenar muscles of one hand it was found that there was scarcely a flicker of contraction in the short abductor and opponens pollicis. In order to relax these muscles the thumb was splinted in opposition, and after four months' treatment they had so developed that she was able to abduct and oppose her thumb strongly against resistance. After the initial lesion many damaged anterior horn cells no doubt recovered, but the muscles they supplied were so overstretched that paralysis persisted. When they were placed at a mechanical advantage, and controlled voluntary movement was encouraged, recovery occurred in response to the functional demand. Other equally striking examples could be cited from a group of fourteen late cases. Because of this, operations for joint stabilization should not be considered until a thorough attempt has been made to obtain maximal improvement. If this is not done there is a grave risk that one will excise a joint and find later that the operation was unnecessary, the muscles having become stronger after the arthrodesis which gave them the relaxation necessary for their recovery. This point is well illustrated by the following cases:

* As fourteen of these had been treated for some months before admission they have not been included in the group considered under the heading of "Recovery Period."

Muscle chart of the lower extremity for recording progress of cases under treatment

The Patients

The patients studied were admitted to the Royal National Orthopaedic Hospital, Stanmore, Middlesex, between the years 1932 and 1936. Their ages ranged from 4 to 14 years, so that they were old enough to co-operate in both charting and treatment. The lesions were probably more severe than those of the average type seen in the London area during those years. Some cases admitted from orthopaedic clinics were of average severity, but others were, transferred from general and fever hospitals because of extensive paralysis calling for prolonged treatment.

apt to be affected by one's optimism or pessimism at the time, and the patient is easily deluded by trick movements so readily acquired and accounted as recovery. No one can remember for long the state of all the important muscles, and even when the patient is always seen by the same observer such notes as "extensors of the foot stronger" convey little more than a general impression, and are much less informative than a muscle chart. The keeping of a chart also eliminates the personal factor from the records, and is therefore invaluable if another clinician is called upon to treat the case.

able. Preliminary results are encouraging, and such a process has manifestly so many advantages that work to this end will be continued.

3. *Disinfestation of Furniture and Clothing.*—A van process of disinfestation, using heavy naphtha, has been developed which promises well. So far it has not had an extended trial, but the preliminary results are satisfactory. Further work is in hand.

4. *Reaction of Workmen using Naphtha in Disinfestation Work.*—Complaints by workmen have been almost negligible. One man developed a slight skin irritation on the hand, but this has been cured by the use of lanolin, and, generally speaking, the men have taken kindly to the use of naphtha as a fumigant.

The earliest experiments with heavy naphtha and much of the subsequent work described in this paper were made possible through the interest and co-operation of Dr. J. Macmillan, medical officer of health for the borough of Woolwich. We wish to express our indebtedness to him for the use of houses, equipment, and the services of members of his staff.

All the work on heavy naphtha has been carried out for the Medical Research Council under the auspices of its Bed-bug Infestation Committee.

THE RECOVERY PERIOD IN ANTERIOR POLIOMYELITIS

BY

NORMAN M. HARRY, M.S., F.R.C.S.

House-Surgeon, Royal National Orthopaedic Hospital, Stanmore

No big epidemics of anterior poliomyelitis have been recorded in England, yet on an average 640 cases occur annually, and the more severe of them present an important medical and economic problem.

It is well known that many patients improve greatly after the acute illness has subsided. However, observers disagree on the length of the period of recovery when adequate treatment is given. Some state that it is as short as nine months, others as long as four years. There is therefore some uncertainty regarding the proper duration of hospital treatment; and when spinal, abdominal, and lower limb muscles are involved it is even more difficult to decide when patients should be allowed to walk. In order to avoid the possibility of insufficient treatment it is best to err on the side of safety, and keep them in bed while there is any possible hope of improvement. This means that some patients are treated in hospital for a longer time than is afterwards found to be necessary. Economic considerations are involved, for the cost of keeping a patient in hospital is at least two pounds a week, and another person is for the time being deprived of the bed. More accurate information on the length of the recovery period is needed before this essential margin of safety can be reduced.

Although a huge American literature on poliomyelitis has accumulated during the last twenty-five years, most of it is devoted to descriptions of various forms of treatment and comparatively little to analysis of the results. In the Royal National Orthopaedic Hospital, since 1932, the progress of patients with infantile paralysis has been carefully recorded on muscle charts, which have provided the data for this study. The value of these charts in the prognosis and treatment of poliomyelitis has not been sufficiently appreciated in England, and it is to be hoped that they will be more generally used.

In the present investigation I have determined the progress of paretic and paralysed muscles in thirty-six patients all receiving the commonly accepted treatment from the time of the acute infection. The data so obtained are important in arriving at a prognosis regarding the degree of muscle recovery, and when the lower limbs are involved this affords a guide in deciding when to begin ambulatory treatment.

Treatment

During the acute phase of the disease a patient is given absolute rest in either a plaster shell or a complete plaster case. In this way the damaged anterior horn cells are shielded from stimuli on the sensory side and from the patient's desire to move the part. This period of rest during the stage of acute inflammation is in accordance with general pathological principles, and in practice is approved by competent observers who have dealt with many cases. When muscle tenderness has gone one infers that the acute inflammation in the cord is subsiding. Muscle re-education is then started in conjunction with radiant heat and massage, while joints are moved, passively if necessary, to prevent stiffness. Particular care must be taken to avoid fatigue of the recovering muscles, and when exercises are not being carried out, overstretching of the weak muscles is prevented by resting them in plaster shells or splints. Light tasks are imposed on muscles too weak to function against gravity. In many instances the exercises are carried out in warm-water baths, gravity being eliminated thereby, while the heat improves the circulation. In a few instances electrical stimulation is an additional therapeutic measure, valuable when there is one weak muscle in a group the other members of which have the same function but are not paralysed. For example, the biceps femoris, semimembranosus, and semitendinosus are flexors of the knee. When these muscles are involved it may be found that the semimembranosus and semitendinosus are strong enough to flex the leg against gravity, while the biceps shows scarcely a flicker of contraction. Under these circumstances active flexion is performed by the stronger muscles, and the biceps is not used; electrical stimulation of the latter is therefore indicated. But, wherever possible, reliance is placed on voluntary exercise, which is the only true form of muscle re-education.

The Muscle Charts

The progress of cases under treatment was recorded on muscle charts introduced into the hospital by Mr. H. J. Seddon, the resident surgeon. At first charting was done every two months, but is now carried out at intervals of six weeks. The chart here shown is used for the lower extremity. The skeletal muscles are classified into forty groups, and the voluntary power of each is tabulated as N; R+; R-; G-; F; or O. R+ signifies that the muscle will overcome gravity and additional resistance, but is less powerful than normal. R- indicates that it will overcome gravity but not additional resistance. G- is recorded if the muscle will carry out its action only when gravity is eliminated; while F means that there is a flicker of contraction insufficient to move the part. Since the only movement of use to the patient is that which he initiates voluntarily, the recording of voluntary power is a more direct measure of recovery than that obtained by electrical stimulation. Such a chart has the merit of showing improvement or retrogression accurately enough for clinical purposes, without the use of special apparatus such as that devised by Lovett. With a little practice the necessary observations can be made fairly quickly.

months' treatment the anterior and posterior tibial muscles showed only a flicker of contraction, yet in three years they were able to invert the foot against gravity. Steady progress occurred during that time as the child gradually learned to co-operate. Acute illness or joint stiffness may also affect both the rate and duration of recovery. This was noticeable in a patient who developed scarlet fever during the re-education period. The toxæmia caused a definite decrease in muscular power, which was regained as the infection subsided. Later the child suffered from acute suppurative otitis media and a similar phenomenon was again observed.

The decision as to when ambulatory treatment may begin depends on the condition of the lower limb muscles and those of the abdomen and spine. The problem is relatively simple if only the former are affected, but when asymmetrical abdominal or spinal paralysis is present there are many difficulties. If the limbs alone are affected the patient should be kept in bed until three successive muscle charts, made at intervals of six weeks, show no further improvement. Patients with slight paralysis usually improve rapidly, and it is safe to allow them up as soon as the muscles will contract strongly against resistance. Six months after the acute infection those who are more severely paralysed may still have very weak muscles. As has already been shown, the ultimate prognosis in these cases can usually be given fairly accurately after one has studied the charts. If there is any prospect of obtaining useful recovery in key muscles extended treatment should be given, but in a small proportion of cases this expectation will not be realized and successive charting will show that progress has ceased. The patient should then be allowed to walk with suitable supports. The majority will be doing so within a year from the beginning of treatment.

The R+ curve shows the number of muscles that improved to R+ during each successive period of two months. The curves R- and G- show the number of muscles increasing in power to R- and G- respectively. It will be seen that a maximal number of muscles increase to R+ at the four-months period, that at six months only half the number did so, while after a year very few increased to R+.

It was previously stated that when abdominal and spinal muscles are involved there is difficulty in determining the optimum time for treatment in recumbency. In the first place there is no simple and very satisfactory way of recording the degree of recovery in the abdominal or the individual spinal muscles. Asymmetrical recovery, with or without the influence of gravity, frequently results in scoliosis, which may be slight when first noticed as the patient lies in bed but rapidly progressive when he walks about. Even if he is kept in bed until recovery of muscle power is maximal there is no guarantee that with asymmetrical paralysis the balance between muscles on each side of the spinal column will be improved. Indeed,

in many instances it is further upset, since the less damaged muscles recover more rapidly than the weaker ones. Once deformity is produced the less powerful muscles, being overstretched, become still weaker; thus a vicious circle is established. This helps to explain the development of scoliosis in certain cases two or three years after the acute illness. Usually when there is much paralysis of the spinal and abdominal muscles the lower limbs are also involved, so that if one could assume that the former recovered at the same rate as the latter the patients could be allowed out of bed when the legs showed maximal improvement. Probably such an assumption is not justified, since muscle re-education is more easily applied to the limbs and more rapid improvement would be expected in them. Because of this it is sometimes necessary to keep a patient in bed for two years or more if the trunk paralysis is at all extensive. From a purely theoretical point of view progressive scoliosis could be best controlled by preventing weight-bearing during the period of spinal growth. In most instances this is neither practicable nor desirable. It would mean keeping children in bed until they had reached the age of 16 years. A compromise has to be made, and it can be empirically stated that if patients can possibly walk they should not be kept in bed for more than two and one-half years. Spinal and abdominal supports must be given where necessary and methodical examinations made during the next few years. Sometimes a scoliosis progresses rapidly in spite of supports and remedial exercises, and leads ultimately to the vital capacity being diminished and to circulatory insufficiency. When this is found to be occurring, and the patient is over 8 or 10 years of age, he should be admitted to hospital again, and the deformity corrected as far as possible by head suspension. The Fisher frame used at the Royal National Orthopaedic Hospital is an excellent appliance for this treatment. At a later date one might consider the question of spinal fusion in those cases where external support will not prevent progressive deformity, with its unfortunate sequelae.

Summary

1. An account is given of the results of a study of thirty-six recent cases of anterior poliomyelitis, progress of which under treatment was recorded on muscle charts.
2. The muscle re-education period is usually found to be much less than the spontaneous recovery period. In the average case it is from nine to twelve months.
3. At from four to six months after the acute infection it is possible to determine the ultimate degree of recovery with fair accuracy.
4. The methods of treatment are briefly given, and the optimum time for treatment in recumbency is discussed.
5. A plea is made for the general adoption of graduated muscle charts as an aid both in treatment and in prognosis.

My thanks are due to the medical board of the Royal National Orthopaedic Hospital for permission to publish this paper, and especially to Mr. H. J. Seddon for his invaluable help and encouragement.

In September, 1933, a boy aged 8 years suffered from anterior poliomyelitis. Both upper limbs were affected, and he was kept in bed for ten weeks. When seen by a surgeon in January, 1934, the left upper limb had completely recovered, but the right deltoid remained paralysed. A note made at this time read: "No hope for deltoid, will probably need arthrodesis." A splint was not applied, and the deltoid naturally remained paralysed. Thirteen months after the acute infection the patient attended another clinic, where it was found that in spite of the absence of treatment the muscle would contract against gravity but not additional resistance. An abduction splint was supplied, and after six weeks' treatment the deltoid was seen to be capable of contracting against both gravity and resistance. By November, 1935, the muscle had completely recovered, and re-examination in November, 1936, showed that it was normal.

Some years ago a patient upon whom an arthrodesis of the knee had been performed for quadriceps paralysis came under the care of Mr. Bankart. When examined by him the affected knee was soundly ankylosed, but the quadriceps had recovered.

Progress in the Muscle Re-education Period

The following table shows the number of times important muscles were involved together with the percentages of good and poor recoveries under adequate treatment. For the sake of clarity and simplicity I have not given a complete list of the recorded muscles.

Table showing the Result of Treatment in 36 Cases

	Number of Times Involved	After Treatment Completed. Percentage Capable of Contracting at least Against Gravity	After Treatment Completed. Percentage Capable of Moving Part with Gravity Eliminated	After Treatment Completed. Percentage showing no Useful Contraction
Lower limb		Per cent.	Per cent.	Per cent.
Gluteus maximus ..	44	80	9	11
Gluteus medius and minimus	48	57	26	17
Quadriceps femoris	52	54	16	30
Hamstrings	41	65	5	30
Calf muscle	44	69	9	22
Dorsiflexors of toes	46	67	8	25
Anterior and posterior tibials	51	38	6	56
Peronei	45	67	11	22
Upper limb				
Deltoid	15	79	14	7
Triceps	13	70	15	15
Biceps and brachialis	14	100	—	—
Short muscles of humb	13	78	—	22

It will be seen that the chief muscle groups of the lower limb were involved with approximately equal frequency, but that some recovered more completely than others. In general the distribution of paralysis and the extent of recovery in individual muscles were not very different from those in certain series of cases recorded in America. The gluteus maximus fared best and the two tibials worst; over 80 per cent. of the former became strong, while over one-half of the latter remained useless. I could not find such a striking contrast in any other series of cases. Generally the gluteus maximus did not do so well and the tibials recovered more completely. Also, it is unusual for the peronei to recover so much more frequently than the tibials. It is possible that in the present series better results might have been obtained

in the tibials had the feet been more carefully splinted in inversion during the re-education period and the soles supported by accurately moulded plaster gutters.

Early Recovery

The most rapid improvement in voluntary power takes place during the first six months after the acute illness. Indeed, in those cases in which the ultimate function was good, surprising recovery was found after the initial six or eight weeks of complete rest. Under muscle re-education during the next four months there was a further marked increase in strength. However, no certain prognosis could be given during this period except in mild cases, and in the most severe where all the muscles of a limb remained completely paralysed after four months. In the ten instances where all muscles of a lower limb were charted as O or F at four months the extremity remained flail.

Recovery at Six Months

Interesting facts emerged when the condition of three hundred muscles at the end of the six-months period was compared with their ultimate state.

I. Those which contracted against gravity and resistance (R+) at the end of six months became more powerful, and many were eventually regarded as normal.

II. All muscles capable of contracting against gravity only (R-) became strong enough to move against additional resistance (R+).

III. Of the group that were able to move the part only when gravity was eliminated (G-), (a) 45 per cent. recovered sufficiently to contract against gravity and resistance (R+); these were initially the stronger muscles; (b) 45 per cent. were ultimately able to contract against gravity only (R-); (c) 10 per cent. did not improve.

IV. Of those showing only a flicker of contraction (F) 90 per cent. failed to improve, while 10 per cent. became powerful enough to contract against gravity (R-). Briefly expressed, the majority of muscles which after six months were capable of moving the part developed useful contractions, while most of those that could not do so failed to recover. Therefore, at six months from the onset of the acute infection it is possible to predict the ultimate extent of recovery with reasonable certainty.

Reading at Six Months	Ultimate State
R+	N or R+
R-	R+
	R+ : 45 per cent.
G-	R- : 45 ..
	G- : 10 ..
F	R- : 10 ..
	F : 90 ..

In this series of cases improvement continued until nine to eighteen months from the acute infection, and in odd cases even longer, but in the vast majority no great change was seen after a year of muscle re-education. It may be true that the period of spontaneous recovery is from two to four years, but the period of notable improvement is much shorter when adequate treatment is given from the first.

Some cases progress differently from those considered here. Young children who cannot co-operate fully in the muscle re-education may show a relatively slower improvement over a longer period than those who are older. This is well illustrated in the case of a child aged 2 years at the time of the acute infection. After nine

The knees are held in slight flexion by small pads. If possible, all the bed-clothes are kept off the patient by a large cradle and the air is kept artificially warmed.

(3) Every two hours the painful muscles are fomented, or short-wave diathermy is applied. After that the limbs are passively moved through the full range of each joint three times. At first the limb may be exquisitely painful, but the pain soon disappears and never persists for longer than three days. During the night the limbs are not moved, but are allowed to remain in the position described, and are inspected every two hours by the night staff. If they are out of position they are replaced once again. If pain causes sleeplessness, fomentation and manipulation is carried out during the night. The patient must be under observation night and day. A remarkable feature of this treatment is the quick change in the mental and physical condition. A sick child, apprehensive of painful manipulation, is converted into a contented and co-operative individual within three days.

Active Treatment in the Apyrexial Stage

As soon as the temperature falls the active phase of the treatment is begun, and may be summarized thus:

- (a) The individual treatment of the patient and maintenance of a cheerful mental outlook.
- (b) Special form of hydrotherapy.
- (c) Maintenance of impulse.
- (d) Avoidance of fatigue.
- (e) Avoidance of immobilization.

This active phase is instituted with extreme care, because it must be remembered that most of the residual anterior horn cells are still in a state of cloudy swelling. The patient must be treated alone because it is of major importance that the whole attention should be concentrated on the treatment and not diverted elsewhere. Above all, an atmosphere of confidence must be maintained. The patients are placed upon a canvas sheet and lowered into the bath, and given the form of hydrotherapy previously described. The joints are moved passively every two hours, and on only one occasion each day is an active attempt at movement of the affected muscles made. If a limb shows extensive paralysis only one muscle group is exercised at a time, the other muscle groups being exercised at later intervals in the day. The active attempt at movement involves a special re-educative technique and is carried out as follows:

The limb is grasped firmly just below the insertion of the paralysed muscle or muscle group, and the patient is asked to make the movement. Special grips are used to prevent accessory or trick movements. The patient focuses all his attention on the affected muscle, and the attendant slowly performs the movement passively. Within a few days a trained assistant will detect a faint change in the affected muscle. It can be detected long before the finest movement is noticeable, it represents the first stage in the return of tone (subliminal excitation) in the muscle, and is termed "the impulse."

It takes some training to recognize at first this impulse, which is the basis of the re-education technique. It is the small flame of returning muscle tone which must be delicately nurtured or it will disappear. As the impulse strengthens active attempts must be made twice a day, later three times a day, and finally six times a day. When a movement is achieved for the first time it must be done only once a day, but as it improves the number of times is increased to four a day. The assisted movements are done at first in the bath under water, because the water

gives the patient greater mental consciousness of the position of the limbs, but later on the special tables. They are assisted movements at first, but when they strengthen they are resisted, and this practice is maintained until maximal power is achieved.

Once each day in the early stages the patient is taken out of bed and the feet are placed on the ground. A few days later a little weight is allowed on the feet. As muscle power returns more and more weight is allowed on the feet for very short periods each day. This procedure brings about proprioceptive re-education of the lower extremities and re-establishes the blood supply of bones and joints. Full details cannot be given here on the whole re-educative technique, but are available in Elizabeth Kenny's *Infantile Paralysis and Cerebral Diplegia* (1937, Angus and Robertson Ltd., Sydney). Only when a patient still showed paralyses after about two years' treatment would the application of splints or operative intervention be considered.

Avoidance of Fatigue

It is of extreme importance that fatigue be avoided, and this is the reason for the delicate gradation of the re-educative system. If, for example, a small movement is achieved for the first time, it must not be attempted again for a full twenty-four hours or it may disappear for weeks. Similarly, eliciting the impulse more than once or twice a day during the early stages of treatment may cause it to disappear entirely. The estimation of the faradic and galvanic responses may cause the impulse to disappear for weeks. Thus the attendant must be able to judge exactly by touch the amount of impulse present. Any unskilled attention in the early stages will lead to failure. Extreme care is essential in the nursing of paralysed muscles of the shoulder girdle, especially the deltoid muscle. Intensive training of a competent staff is essential.

Results of Treatment

It is not, and never has been, claimed that this treatment will cure all cases at all stages of the disease. So far only thirty-five cases have been treated in the early stages, but in view of the degree of improvement in these and in 1,400 chronic cases, it is claimed that Sister Kenny's methods will give the maximum recovery possible in every case treated within the first two months of the disease, this has not always been achieved by orthodox methods. A feature of the method is the speed of improvement, which allows the period of hospitalization to be reduced. Under treatment no case, either acute or chronic, has developed deformity, nor have there been any trophic manifestations, such as chilblains or impairment of the growth of a limb.

Criticism of Orthodox Methods

In the acute stage emphasis is not placed enough upon maintenance of circulation, only one-half to one hour a day being allotted to this: for the remainder of the time the limb suffers from acute anoxia, and this leads to a spasm in the unaffected muscles, stiffness of joints, and contraction of fasciae. Splinting aggravates this greatly and causes marked impairment of normal proprioceptive sensibility. Splinting may prevent major deformities, but it accentuates muscle spasm and actually predisposes to the development of minor deformity. It also has a bad psychological effect. Many cases after only a month's splinting have shown stiffness of joints and early muscle contractures. Cases immobilized for more than two months are more difficult to re-educate effectively.

TREATMENT OF ACUTE POLIOMYELITIS

AN ANALYSIS OF SISTER KENNY'S METHODS

BY

F. H. MILLS, M.B., B.S.

Formerly Tutor in Medicine, St. Andrew's College, University of Sydney

The treatment of infantile paralysis has long been inadequate, and statistics show that of muscles paralysed in the acute stage approximately 60 per cent. of the upper limb muscles and only 30 per cent. of lower limb muscles recover completely; the figure for the trunk muscles is somewhat higher than that for the upper limb. Although the figures vary in different epidemics, approximately 25 per cent. of cases make a complete recovery in three years, leaving a majority with some residual paralysis. These cases are complicated by trophic changes, and deformities which may arise from muscle imbalance. Any form of treatment which will reduce the amount of paralysis in this the "saddest of diseases" will be greatly welcomed. The new system of treatment which I am about to describe has produced results so promising that it appears that we may have to change our views as to the degree of recovery possible. This system has stood the test of over twenty years' experience in the treatment of both acute and long-standing cases, and in no instance has trophic change or deformity developed.

Orthodox Methods of Treatment

The accepted or orthodox methods of treatment may be summarized as follows:

- (a) Rest and immobilization of the affected limbs until the stage of pain or irritation is past.
- (b) Maintenance of affected muscles in a position of relaxation.
- (c) Avoidance of contractures and deformities by light retentive apparatus.
- (d) Massage and active and passive movements.

Treatment along these lines is based upon the theory that the pain in the limbs is of central or meningeal origin, and that rest and immobilization will remove the harmful afferent stimuli and enable reparative changes to take place in the cord. The stage of irritation or painful period lasts on an average six weeks, and may be prolonged for three to six months. Immobilization and rest during the whole of this stage is not considered detrimental by many authorities.

Principles of the Sister Kenny Treatment

In opposition to this accepted theory the view is taken that the pain in the extremities is almost completely vascular in origin. Some of the pain may be of central origin, but this takes the form of spontaneous or root pain and is not aggravated by movement. The muscular pain results from venous engorgement and consequent anoxia of the paralysed muscles. The venous return from the extremities is influenced mainly by muscle tone and activity. In poliomyelitis the interference with this venous return is often of extreme degree. At first there is venous stasis, and later on capillary stasis and capillary paralysis; this is manifested by the coldness and cyanotic appearance of the limb, and is accentuated by immobilization and splinting, especially in the position often adopted of abduction of the upper or lower limb. As a result mild trophic changes develop in the skin, bones, joints, fasciae, and especially in the muscles. Immobilization of paralysed

limbs, with consequent vascular catastrophe, leads to contraction of the muscle sheath and anaemia of muscle fibres, with subsequent mild fibrosis—seemingly a clinical entity, comparable to a very mild Volkmann's ischaemic contracture. Brooks has demonstrated the fact that complete obstruction to the venous return from a muscle leads in a few hours to profound muscle changes and is the causative factor in Volkmann's paralysis. A parallel may be drawn between the aetiology of the two conditions. The importance of this ischaemic pseudo-paralysis is recognized when it is understood that it renders muscle re-education extremely difficult. It is accentuated both by stretching and relaxation of muscles, as in the position of relaxation the muscle sheath contracts, tending to cause a permanent shortening of the length of the fibres and often resulting in slight deformities.

The irritation stage is an artificial stage, which may invariably be overcome in two or three days by a well-regulated system of frequent passive movement, fomentation, and hydrotherapy. In no case does pain persist more than three days, although it will usually recur in the early mornings after the limb has been rested during the night. Cutaneous hyperaesthesia also disappears under the treatment. As soon as the temperature drops the active phase of re-education is started—that is, re-education is begun within one week of the onset of paralysis instead of after six or more weeks. In those cases in which a slight rise of temperature persists treatment is carried out in spite of the pyrexia.

Massage has little part in the restoration of circulation, to which all efforts must be directed. By massage the blood is merely squeezed from one set of dilated capillaries to another. Only some method by which capillary tone can be re-established is effective (see Sampson Wright, 1936, *Applied Physiology*). Such a method is a system of hydrotherapy which makes use of the rapid alternation of hot and cold sprays in the bath. The limbs become suffused with a pink colour within ten minutes, the areas last to lose their cyanotic appearance being those which overlie the paralysed muscle groups. By this simple measure applied daily trophic changes are avoided and the later application of such operative procedures as sympathetic ramisection rendered unnecessary.

Briefly, instead of being dealt with by rest and immobilization in the acute stage, the affected limbs must be treated energetically, by fomentations, by hydrotherapy, and by movement through every range of each joint every two hours, and a finely graded system of re-education must be started as soon as possible, usually within the first week of paralytic manifestations. Under such a regime wasting of paralysed muscles occurs only to a small degree.

Treatment in the Pyrexial Stage

(1) The usual therapeutic measures, such as lumbar puncture and administration of sedatives and convalescent serum, should be adopted.

(2) The patient lies flat on the back with a very low pillow and a small towel between the shoulders to prevent winging of the scapulae; the limbs are placed in the normal position. The arms are alongside the body supported forward in the mid-horizontal level by small towels, and the forearm is midway between pronation and supination, with the wrists and joints of the hand also in mid-position. The elbow is supported by the towels so that the weight of the humerus does not stretch the muscles of the shoulder girdle. The legs are placed together, no abduction being permitted, and foot-drop and external rotation are prevented by an easily adjustable foot-block.

positive findings in the nervous system. Extending from the coracoid process four and a half inches down the left arm was an old surgical scar. The left arm was two and three-quarter inches shorter than the right, the shortening being limited to the humerus and radius and the ulna. An old scar, two inches long, was seen on the dorsum of the left forefinger, curving proximally to the radial side and extending through the nail, which was deformed.

The patient was admitted to the Gateshead Mental Hospital as a voluntary patient and there given atropine in high dosage, according to the technique of Hall (1935, 1937) after Kleeman. Complete relief from her symptoms was obtained with 4½ mg. daily, spread over three doses. Observation and routine psychological examination produced nothing relevant.

Commentary

Cases of Parkinsonism following poisoning by manganese, gold, cyanide, and carbon disulphide have been recorded, but I have been unable to trace one following poisoning by the substances used in this case for the treatment of the growth at the head of the humerus.

Only upon inquiry was a history obtained of weakness and pain in the interval between the injury and the onset of the tremor, and these had not been regarded by the patient as abnormal. Thus the first feature of Naville and de Morsier is poorly exemplified. But the emphatic story of the tremor beginning soon after the injury, appearing at first only in the injured finger and remaining clearly limited to it for some weeks, is surely significant; and indeed no previously recorded case has shown such a precise local relation between the trauma and the first tremor. Because of this and of such a definite history of excellent general health, and in view of the cumulatively impressive accounts of the condition hitherto published, it would seem unwarranted to postulate an untraceable attack of encephalitis lethargica. Coincidence of occult encephalitis and injury does not explain the previously published cases. Naville and de Morsier (1932) state that "the constant succession of these phenomena—injury, pain, hypertony, and tremor of the injured limb; extension to the homolateral limb, then to the contralateral limbs—enables one to declare that it is not possible for it to be in the nature of coincidence."

The effect of high atropine dosage has not been mentioned in the cases published, and it is pleasant to be able to record its satisfactory action in this case, but it will surely mask any spread of symptoms to the opposite limbs. When the patient was last seen (November, 1937) she was persisting with her atropine treatment, had no complaints, and was able to do a hard day's work.

I am grateful to Dr. C. B. Bamford for his interest and for his permission to publish this case, and to Dr. F. J. Nattrass for confirming the diagnosis of Parkinsonism.

W. B. Hubbard (*Arch. Ophthalm.*, Chicago, August, 1937) has experimented with caustic burns in rabbits using 32 per cent. sulphuric acid and 20 per cent. sodium hydroxide. In all cases one eye was irrigated with tap-water, the other being washed out with either 2 per cent. sodium bicarbonate or 2 per cent. acetic acid to neutralize the caustic. In the case of acid burns the best results were obtained with tap-water, while alkaline lesions were best treated with weak acid irrigations. This difference is probably due to the fact that acid proteinates are insoluble and alkaline proteinates are soluble.

RETENTION OF URINE FOLLOWING EXCISION OF THE RECTUM

BY

H. T. SIMMONS, Ch.M., F.R.C.S.

Research Fellow, The Royal Infirmary, Manchester: Honorary
Assistant Surgeon, Christie Hospital and Holt
Radium Institute

Retention of urine following excision of the rectum is so frequent that it is regarded as a usual post-operative complication. It occurs in both sexes, and generally three or four days elapse before the patient is able to empty the bladder voluntarily. Occasionally the resumption of voluntary micturition is delayed for weeks or even months, and this condition appears to be more especially associated with the removal of high and extensive growths by the perineal route. The danger of retention of urine is the supervention of sepsis, which, though not always fatal, causes considerable morbidity and undermines the patient's strength. Minor operations on the perineum and anal region often give rise to a retention of urine which rarely lasts more than twenty-four hours and which responds to simple treatment. This retention is thought to be due to reflex nervous inhibition. After removal of the rectum, however, the condition persists for three or four days, and occasionally for weeks, and must be due to a more definite interference with the nervous mechanism.

Sympathetic and Parasympathetic Innervation

The filling of the bladder is dependent upon its sympathetic nerve supply, which keeps the internal sphincter contracted and so allows the accumulation of urine. Abolition of this nerve supply, or its inhibition, allows the sphincter to relax and the urine can escape. The emptying is due to the action of the parasympathetic nerves, which cause the bladder to contract and at the same time relax the internal sphincter. Destruction of this nerve supply reduces the contractile power of the bladder and leaves the internal sphincter tonically contracted by the action of the sympathetic nerves, which are no longer opposed. Thus retention of urine occurs.

Normally voluntary control of micturition exists because both these nerve supplies have cortical connexions. If, however, both are destroyed the bladder does not remain completely paralysed. After a latent period the musculature contracts to the stretch-stimulus of the accumulating urine; at the same time the internal sphincter is relaxed by the intrinsic nerve plexus. This automatic bladder is an excellent example of how smooth muscle adapts itself to carry on its original function after the loss of its extrinsic nerve supply. The presacral nerve, lying behind the peritoneum over the promontory of the sacrum, brings the sympathetic nerve supply of the bladder into the pelvis from the lumbar ganglionated cords. This nerve divides into the two hypogastric nerves, which, passing round each side of the pelvis, bring the supply to the pelvic plexuses, joining them near the groove between the rectum and the base of the bladder. The fibres pass through these plexuses and are distributed to the trigone and internal sphincter.

The parasympathetic supply to the bladder is brought by the nervi erigentes. In seven pelvises dissected in the anatomy department of the University of Manchester I found that the nervi erigentes arose mainly from the second and third sacral nerves. In only three cases was there any contribution from the fourth sacral nerve. A pelvic plexus is formed on each side of the rectum by

Massage is inadequate. It does not prevent the development of chilblains and the more severe trophic disturbances in many cases, as does the special method of hydrotherapy. Electric stimulation causes fatigue and damages the recovering cells. The usual technique of re-education is too coarse. The re-education board does not prevent accessory or trick movements which by long facilitation take up the function of the paralysed muscles, which are forgotten and, if severely affected, do not tend to recover. Many of the affected nerve cells do not redevelop their synaptic relationships, and lie dormant or die. No method of re-education can be successful which does not prohibit all accessory movement, concentrate only on affected muscle groups, and produce mental co-operation between patient and attendant. This can only be done through the sense of touch, which can be refined to the point of recognition of the impulse. Full concentration on the part of the patients can only be elicited by solitary treatment, and by assisting the patient by sensory means to visualize the exact muscles to be treated.

Summary

In view of the results obtained by the Sister Kenny method we feel that the prognosis in acute poliomyelitis as regards recovery of function is better than has formerly been thought.

Recovery of muscles is retarded or prevented by ischaemic changes which occur if they are immobilized during the first few weeks of the disease; maximal power can only be achieved by hypertrophy of the residual muscle fibres.

The usual re-educative methods are not sufficiently specialized and do not fully avoid fatigue and trick movements; consequently the muscles do not regain function to the fullest extent possible.

It is suggested that deformity is caused by ischaemia and the consequent muscle spasm and fibrosis, which is, paradoxically, accentuated by splinting, especially when applied in the early stages.

The following medical promotions in and appointments to the Venerable Order of the Hospital of St. John of Jerusalem were announced in the *London Gazette* of January 4: as Commanders, Major-General E. W. C. Bradfield, C.I.E., O.B.E., I.M.S., Dr. John Ramsay, C.B.E., Major-General Sir Frank P. Connor, D.S.O., I.M.S.; as Associate Commanders, Dr. D. H. Mehta, C.I.E., Lieutenant-Colonel K. K. Chatterji, F.R.C.S.I.; as Officers, Major N. F. C. Burgess, M.D., Dr. S. A. Wilkinson, Lieutenant-Colonel J. Rodger, O.B.E., M.C., I.M.S., Colonel N. M. Wilson, O.B.E., I.M.S., Major-General E. A. Walker, K.C.I.E., C.B., I.M.S., Dr. E. E. Dufty, Mr. H. J. Paterson, C.B.E., M.C., Dr. C. D. Newman, Dr. J. F. Fitzmaurice, Colonel J. A. S. Phillips, C.I.E., I.M.S., Professor W. I. Gerrard, O.B.E., the Hon. R. D. Fitzgerald, M.C., M.D., Dr. J. S. Webster, as Associate Officers, Lieutenant-Colonel A. M. Sharma, I.M.S., Dr. K. B. A. Hamid, Lieutenant-Colonel M. S. Joshi, I.M.S., Dr. S. C. Chatterjee, Colonel N. S. Sodhi, M.C., I.M.S., Captain F. N. Kapadia, M.D., Major V. V. Krishnamoorthy, M.B., Dr. J. V. Karve, Dr. S. D. de Vos; as Serving Brothers, Dr. R. J. Dyson, Dr. E. W. Rees-Jones, Dr. H. Ramsden, Dr. H. B. Pare, Dr. L. D. Porteous, Dr. H. Hunt, Lieutenant-Colonel G. H. Mahony, I.M.S., Major F. T. Deatker, I.M.S., Dr. J. E. Dovey, Dr. R. C. Oehlers; as Associate Serving Brothers, Captain M. E. Pavri, L.R.C.P., Dr. S. W. Patil, M.B.E., Dr. B. W. Advani, Dr. P. C. Roy, Dr. R. B. V. V. Mulay, Dr. Li Shan Fan, Dr. A. Wai-Tak Woo; as Serving Sisters, Dr. Florence F. Sexton, Dr. Agnes M. Glover, Mrs. Agnes L. J. Dovey, M.B.

POST-TRAUMATIC PARKINSONISM AND THE EFFECT OF ATROPINE

BY

T. F. MAIN, M.D., D.P.M.

Deputy Medical Superintendent, Gateshead Mental Hospital, Stannington

Since the review of forty-two cases collected from the literature by Naville and de Morsier few records of this condition have been published. Faure-Beaulieu (1932) gives a detailed account of one case, and finds himself in close agreement with the findings and conclusions of those authors, that such a syndrome indeed exists and that it presents the following features: (i) in the interval between the injury and the appearance of the Parkinsonian syndrome the injured limb remains weak, painful, or paraesthetic; (ii) tremor and rigidity almost always begin in the injured limb; (iii) the syndrome then extends to the other limb on the injured side, so that at a certain stage the aspect is one of hemi-Parkinsonism; (iv) there are no mental changes.

More recently Walker (1937) and Hodgson (1937) have published one case each, and J. H. Hebb, Director-General of Medical Services, Ministry of Pensions, has found fit to query the existence of such a syndrome in view of the medico-legal consequences of its recognition. The details of the following case may therefore be of interest.

ILLUSTRATIVE CASE

A single woman aged 25 was seen in July, 1937, at the Gateshead Psychiatric Clinic of the Royal Victoria Infirmary, Newcastle-upon-Tyne, suffering from weakness and tremor of the left arm, which was suspected by her doctor to be of a hysterical nature. Three years before, while chopping wood, she had struck the tip of her left forefinger with an axe, so that "the end was hanging off." This had healed in about three weeks, and a fortnight later trembling was noticed in the injured finger. Her hand was clumsy—it "dropped things easily"—and in about three months it too began to shake, while a week or two after this the whole forearm and arm became involved. Two weeks later she noticed her left foot "kicking stones on the ground when she walked." The limbs on the left side then "lost their energy," and this and the trembling of the arm got worse, so that for the last two and a half years she could do little physical work of any kind.

Inquiry into her history elucidated former (surgical) trauma to her left arm. In November, 1918, and again in October, 1919, Mr. Grey Turner operated on the head of her left humerus, scraping out a growth which was proved histologically to be a giant-cell sarcoma. On the first occasion he sponged out the cavity with pure carbolic, and on the second washed it out with Harrington's solution and packed it with iodoform gauze soaked in 1 in 18 carbolic. In November, 1919, the wound was reopened, cleaned, treated with bipp, and sutured. An examination in March, 1923, showed no further trouble, and the x-ray report then was, "a piece of metal dressing." Detailed inquiry for any illness which might be construed as an attack of encephalitis lethargica revealed nothing: neither she nor her mother could remember her having even a common cold during the last six or seven years. Her mother said there was no mental change.

The patient manifested the following features of left hemi-Parkinsonism: head bent towards the left shoulder; tremor of the lower lip and left angle of the mouth, more pronounced when she smiled in her slow Parkinsonian way; the left elbow held close to the side, with forearm pronated and tremorous; a pill-rolling movement of the left fingers and thumb; rigidity of the left arm and leg. She adopted a steppage gait for the left leg, and her foot was plantar-flexed. The tendon, abdominal, and plantar reflexes were normal, no sensory changes were revealed, and there were no other

Clinical Memoranda

Abortion Associated with Broad Ligament Cysts and *B. welchii* Infection

Few abortions can have a stranger background than that about to be described.

CASE RECORD

Mrs. M., aged 27, the mother of three children, the youngest being 7 years old, had her last monthly period on September 8, 1937. During October she had hyperemesis, and at the beginning of that month had a shivering attack, following a fall. She was admitted to hospital on October 26 on account of bleeding from the vagina, which started the night before. She looked flushed, her lips were dry and cracked, and the tongue was coated. The respirations were rapid (44 per minute), but there were no physical signs in the chest. The throat was clear and without a rash; her pulse rate was 108 and there was no cardiac bruit; the temperature was 101° F. She had complained of abdominal pain the previous night.

On examination the abdomen appeared to be slightly distended, and tenderness was felt on pressure in the left iliac fossa. There was no dullness in the flanks. Vaginal examination revealed a uterus about the size of a two-months pregnancy, fixed and tender; the cervix was not dilated and there was a foul-smelling discharge. The urine was acid, concentrated but clear, and contained a trace of albumin.

The case was diagnosed as general peritonitis following abortion and immediate laparotomy decided on. Under 0.5 per cent. novocain and gas-and-oxygen anaesthesia (by Dr. Knight) the abdomen was opened in the midline below the umbilicus; no pus was seen. A smear was taken from the visceral peritoneum immediately on opening the abdomen and sent to the pathological laboratory for investigation. On looking into the pelvis a greyish-black sausage-like mass was found on the left antero-lateral side of the uterus. On releasing the tumour it lost its congested look and was seen to be a parovarian cyst filled with clear fluid. There was another cyst, situated posteriorly, which had the left Fallopian tube running above it, and yet another cyst was present beneath, actually pushed down on to the pelvic floor. They were all removed. The superior cyst was the size of a small hen's egg, the middle one the size of a duck's egg, and the inferior one the size of a pigeon's egg. The right ovary was normal; the left ovary was absent.

My impression at the end of the operation was that I had made a mistake in diagnosis, but that laparotomy had been justified by the unsuspected findings. The report from the pathological laboratory came through in due course, and was as follows: "The cysts are simple parovarian cysts. Peritoneal smear: films show Gram-positive bacilli and pairs and short chains of Gram-positive cocci. Culture yields a growth of *B. welchii* and *Staph. albus*." This report was dated November 1: it was therefore five days before the patient was known to be suffering from an infection by the gas-gangrene bacillus.

On the morning following operation the patient aborted, and the placenta had to be removed manually: she was very shocked until this was done. Proseptasine therapy was started—1 gramme three times a day by mouth—and glycerin was introduced into the vagina: she had precordial pain the first post-operative day, but there were no physical signs in the chest. Pitressin was administered in four-hourly doses until flatus was passed two days after the operation; the bowels were moved by enema on the fourth post-operative day. On the fifth post-operative day she complained of pain in the left buttock, and on examination there was a swelling which seemed to be deep-seated in the buttock and to bear an infero-lateral relation to the left sacro-iliac joint. The swelling was fomented and two days afterwards explored, foul-smelling greenish-yellow pus being aspirated. The abscess was thereupon incised

and found to be deep to the gluteus maximus muscle, the cavity in its upper part being bounded anteriorly by the posterior ligaments of the left sacro-iliac joint. A drain was inserted. On the same day the report on the peritoneal smear came to hand, and the patient was given 20 c.cm. anti-gas-gangrene serum.

The report on pus aspirated from the gluteal abscess is as follows: "Films show Gram-positive cocci in pairs, chains, and clusters. Cultures yield a growth of *B. welchii* and *Staph. albus*." Her condition improved after draining this abscess, and she had another 20 c.cm. *B. welchii* serum a week after the first dose. Five units of insulin were given twice a day to act as a tonic.

A week after the gluteal abscess had been drained the patient complained of abdominal pain. Rectal examination revealed a pelvic abscess: this was drained through the anterior wall of the rectum and produced only a tablespoonful of pus. She became afebrile four days later; there was troublesome diarrhoea for a few days. Convalescence was rapid, and she was discharged from hospital thirty-three days after admission. On the day of discharge pelvic examination revealed a uterus firmly fixed in the pelvis and drawn over to the left side. Since she had been afebrile for two weeks the fixity of the uterus was recognized as the result of the pelvic abscess.

SUMMARY

1. Incarcerated broad ligament cysts complicating pregnancy.
2. *B. welchii* infection of the peritoneal cavity present at operation.
3. Possible presence of gluteal abscess before admission to hospital, and the condition primarily a *B. welchii* septicæmia determined by the fall early in October.

Longtown, Cumberland.

R. RUTHERFORD, F.R.C.S.

Pregnancy Associated with an Ovarian Dermoid

The following case history presents some points of unusual interest.

On June 22, 1937, Miss X., aged 16, consulted me. Her last normal period was on March 6. Early in April there was a slight vaginal discharge of blood. On examination the breast signs were inconclusive. Palpation of the abdomen was negative. Bimanual examination, with one finger in the vagina, disclosed the presence of a tense pelvic swelling to the right of the uterus. A tentative diagnosis of unruptured extra-uterine pregnancy was ventured upon.

The patient was sent to Auckland Public Hospital, where a diagnosis of retroverted gravid uterus was made. The displacement was corrected and a ring inserted. No other pathological condition was noted. A few days after her discharge from hospital she again consulted me. On inspection a swelling could be detected in the right lower abdomen. Bimanual examination revealed the presence of a three-months gravid uterus and a freely movable, firm-grounded swelling above the pelvic brim on the right side. The clinical findings suggested an ovarian cyst. An infra-umbilical abdominal incision revealed an ovarian cyst about the size of a cricket ball. On removal the cyst proved to be a dermoid, containing sebaceous material, hair, and cartilage. Following operation the pregnancy continued undisturbed.

Points of interest are: (a) The association of pregnancy with an ovarian dermoid at the age of 16. (b) When the patient was first examined the cyst was intrapelvic. (c) At the time of the second examination (after the retroversion had been corrected in hospital) the intrapelvic lateral swelling had disappeared, having been displaced into the abdominal cavity.

Auckland, N.Z.

J. P. HASTINGS, M.D., M.R.C.P.

the nervi erigentes, and fibres could be traced down to the anus and as high as the recto-sigmoid junction. The plexuses were attached to the rectum only by their fibres of distribution, and, passing forwards, they communicated with each other and received the sympathetic fibres near the prostate and bladder base. Dissection of the plexuses, and the tracing of the fibres as completely as possible, showed that those arising from the second sacral nerve appeared mainly to supply the bladder, whereas the rectum was chiefly supplied by the lower fibres of the third sacral nerve and the contribution from the fourth nerve.

Operative Injury to Nerves

In the dissecting room the rectum may be removed without the risk of damage to the nervi erigentes or to the pelvic plexuses. The hypogastric nerves which carry the sympathetic supply are in no danger of being injured. The removal of a carcinomatous rectum in a living patient demands, however, a much wider dissection. It was found in the cadaver that the dissection necessary would assuredly destroy the contribution to the pelvic plexuses from the fourth sacral nerves and the lower fibres from the third nerves. During the operation the upper fibres from the third sacral nerve were in constant jeopardy, depending mainly on the height and lateral extent of the excision. Damage to the fibres arising from the second sacral nerve could be avoided, but where a high removal was attempted they were in danger of being divided.

The dissections suggested that in perineal excision of the rectum there is little interference with the sympathetic supply of the bladder, but that the nervi erigentes always suffer some damage. The parasympathetic fibres arising from the fourth, and the lower fibres arising from the third, sacral nerves are usually divided, but as they appear mainly to supply the rectum their division does not affect the bladder to any great extent. The supply to the bladder from the upper fibres of the third sacral nerve suffers from traction, and to a varying degree from actual severance of fibres. The supply from the second sacral nerve is injured usually only by traction, but in the removal of high growths it may be severed. The effect of traction will be to paralyse temporarily, and of severance to paralyse permanently, the bladder parasympathetic supply. Hence the action of the sympathetic nerves will be unopposed, giving in the first case a temporary and in the second case a more or less permanent tonic contraction of the internal sphincter. The resulting retention of urine will be temporary in the first instance and more lasting in the second; but it will hardly become permanent, as the smooth muscle will slowly adjust itself to the altered conditions and give an automatic type of bladder.

Previous attempts to deal with this retention of urine have been mainly concerned with the methods of emptying the bladder when the condition is established. The best results appear to have been obtained by Cuthbert Dukes (1928-9), who suggested the pre-operative administration of two doses, at weekly intervals, of a vaccine prepared from the bacteria present in these urinary infections. He inserted a catheter at the time of operation and afterwards emptied the bladder frequently. The catheter was connected to an apparatus which allowed repeated bladder-washing to be performed, and had a column of antiseptic fluid as a seal for the catheter instead of the customary wooden peg. He demonstrated an immediate improvement in results; but even in his own cases one-third of the males and all the females developed some urinary infection. The danger of urinary infection would

cease to exist if we could avoid the introduction of a catheter into the bladder.

Cause of the Retention

It has been shown that the cause of the retention of urine is a relative overaction of the sympathetic nerve supply of the bladder. This appears to be due to weakening of the parasympathetic supply by traction on its fibres during the operation or, in extreme cases, by actual severance of the nerves. The overaction could be avoided by dividing the sympathetic supply either at the time of excision or at a previous operation. This is easily achieved by the division of the presacral nerve, and we know from the numerous cases in which it has been done for gynaecological pain that it is followed by no untoward effects upon the bladder, even though that organ has an intact parasympathetic supply.

This presacral neurectomy involves no separate intervention. Its performance is very easy and it adds no more than a few minutes to the time taken by the exploratory laparotomy and colostomy which must precede the perineal excision. The presacral nerve is found behind the peritoneum overlying the promontory of the sacrum. An incision two inches in length is made through this peritoneum, the pelvic colon being held well over to the left side. The nerve is formed near the bifurcation of the aorta by the junction of three descending roots, and it passes down into the pelvis either as a single cord or, more commonly, as a loose plexus. Rather more than one inch of the nerve is excised, and to make sure that all the fibres are divided it is better to clear the angle between the right common iliac artery and the left common iliac vein completely of all fatty and fibrous tissue down to but not below the sacral promontory.

Results

A consecutive series of twenty-two cases of perineal excision of the rectum have had their presacral nerves excised at the preliminary laparotomy. Fifteen were males and seven were females, and there was no mortality in the series. In no case was a catheter inserted into the bladder as a guide to the urethra, as it was felt that this was unnecessary and only introduced a risk of sepsis. Of the seven women four passed urine naturally and three had to be catheterized, one for two days and the other two for three days. Of the fifteen men nine passed urine of their own accord; four were catheterized for one or two days, and the other two for five days. In each of these cases the prostate gland was larger than normal. All the patients passing urine normally escaped urinary infection.

These results, although not completely solving the problem of post-operative retention of urine after perineal excision of the rectum, suggest that a preliminary division of the sympathetic nerve supply of the bladder is of considerable value in avoiding this troublesome complication.

Summary

Retention of urine following perineal excision of the rectum appears to be caused by a nervous imbalance—a sympathetic preponderance due to trauma to the parasympathetic supply (the nervi erigentes).

Resection of the presacral nerve at the time of the preliminary laparotomy and colostomy has been followed by a considerable diminution in the incidence of post-operative retention of urine.

REFERENCE

Dukes, Cuthbert (1928-9). *Proc. roy. Soc. Med.*, 22, 259.

The author has, of course, since radiology is a department of medicine, to deal fully in his book with the general legal position of doctors. He therefore summarizes the law of contract and negligence as it affects the doctor; the law of agency, with its implications of vicarious responsibility for assistants and nurses; the law of evidence, and more particularly of x-ray films as evidence; and gives useful, down-to-earth advice for the radiologist who is required to testify in court. In short, this book receives full marks and is highly recommended to English radiologists, with the proviso that, although the principle underlying the American systems of law is much the same as in this country, the reader must make allowance for differences in details of procedure. The book must have been extremely difficult to write, because law and practice vary considerably among the many States of the Union, and the mass of reported cases is enormous and bewildering. There is a good bibliography and table of cases.

PROFESSOR DREYER

Georges Dreyer: A Memoir by his Wife, Margrete Dreyer. With an introduction by Sir Charles Sherrington, O.M. (Pp. 249; 8 illustrations. 10s. 6d.) Oxford: Basil Blackwell. 1937.

This is a charmingly written account of the late professor of pathology at Oxford showing the happy home life of a busy and enthusiastic scientific worker. Dreyer, though a Dane by descent, had several associations with the country of his later life: born at Shanghai, he was thus nominally a British subject; his uncle was president of the Astronomical Society, and two cousins are respectively an admiral and a major-general in the British Navy and Army. Originally anxious to follow his father's profession, the Danish Navy, he was first drawn to medicine by his experience in a very severe attack of scarlet fever. Educated at the University of Copenhagen, he became a demonstrator under Salomonsen, and did much work on ultra-violet rays with Finsen. Among the visitors to the Copenhagen laboratories were Professor W. Bulloch and Dr. E. Frazer of the London Hospital, and thus it came about that he visited England and worked at Oxford, especially under the late Professor Goitch.

In 1907 James Ritchie, who since 1902 had been the first professor of pathology, left Oxford to become superintendent of the laboratories of the Royal College of Physicians of Edinburgh. This changed the place but not the character of Dreyer's activities, for, though his prospects of such a chair in Copenhagen were good, he was attracted to the life at Oxford which he knew, and was elected from the other "possibles," among whom was the late Sir F. W. Andrewes.

The wide field of his scientific work, especially on standards, and his happy faculty of attracting and inspiring young collaborators are shown in this volume, which begins with a pleasantly reminiscent introduction by his colleague, Sir Charles Sherrington.

CLINICAL CHEMISTRY

Chemical Procedures for Clinical Laboratories. By Marjorie R. Mattice, A.B., Sc.M. (Pp. 520; 90 figures, 2 coloured plates. 30s. net.) London: Henry Kimpton. 1936.

The rather cumbersome title *Chemical Procedures for Clinical Laboratories* is perhaps less happily chosen than is the material out of which this book is compiled. Nowadays the better textbooks of this kind do not differ very greatly over a wide range in the methods they choose for presentation. We do not propose, therefore, to make a detailed commentary upon the author's main

material, but rather to single out for mention some distinguishing features of her work. The first of these are the concise notes which follow the description of each method and which are carefully designed to guide the inexperienced over the difficulties and pitfalls that are likely to beset them. The notes, however, cover technical matters rather than general principles, and we feel that the latter could have been given more emphasis.

In a very full section on blood analysis the author's contributions to the accurate determination of creatinine should command special attention, while the part devoted to the urine is chiefly notable for the end chapter, which ably deals with an often neglected topic—namely, the detection and estimation of the heavy metals, not only in urine, but also in the other biological fluids. The author has also taken considerable trouble in the preparation of the fourth section, embracing miscellaneous biological fluids, and has collected very complete information upon their exact composition. She may rightly claim that it is done with a thoroughness not attempted by any other book, and indeed much of the tabulated data is not readily accessible anywhere in the literature. A valuable appendix includes a chapter on the calculation of results and errors, introducing the student to the use of statistical formulae. Here again we have evidence of the author's determination that the book should lack nothing that is essential to the full understanding of analytical methods.

OPERATIONS ON THE EYE

A Textbook of Ophthalmic Operations. By Harold Grimsdale, M.B., F.R.C.S., and Elmore Brewerton, F.R.C.S. Third edition. (Pp. 322; 105 figures. 17s. 6d. net.) London: Baillière, Tindall and Cox. 1937.

The third edition of Grimsdale and Brewerton's textbook on ophthalmic surgery shows a radical departure from the previous editions in the elimination of much that is only of historical interest. In this sense the earlier editions had a completeness which the present edition lacks, but the deletion of matter of historical value has not been carried to the extreme of leaving the reader without a guide as to the evolution of present-day methods. The final result is that the book is more practical without having lost its individuality. The broad conception and wide sweep which pervaded the two earlier editions are left, and thus the student has still at his disposal the means of judging why modifications in operative procedure have been developed and why so many of these are stillborn. By drastic revision room has been found for bringing the subject-matter up to date, the most obvious addition being, of course, the section dealing with detachment of the retina.

A point of weakness in the book is that in their obvious fairness to other surgeons the authors have kept their own vast experience and surgical judgment in the background, allowing the various innovations of operative technique to speak for themselves. To the non-expert reader this has the disadvantage of not giving a clear lead as to which methods are routine procedures. A little dogmatism would not have been out of place. One aspect of modern work does not seem to have received due attention. Plastic operations used to be, and perhaps still are, an important part of ophthalmic surgery. The great changes that have taken place in this field are not clearly reflected in the present work—cases in point being the operations for ectropion and ptosis. These are, however, minor flaws in a book that has been an established guide for a quarter of a century. A word of praise is due to the hand drawings; in their clarity, economy, and effectiveness they are fit companions to the text-matter.

Reviews

SURGERY OF THE CHEST

Thoracic Surgery. By Ferdinand Sauerbruch and Laurence O'Shaugnessy, F.R.C.S. A revised and abridged edition of Sauerbruch's *Die Chirurgie der Brustorgane*. (Pp. 394; 15 plates, 215 figures. 50s. net.) London: E. Arnold and Co. 1937.

It has become commonplace to point to the enormous progress made in thoracic surgery. Indeed, the developments are so rapid that it is hardly possible to write a textbook on the subject that is up to date in all respects at the time of publication. But such books generally suffer from yet another defect. The artificial distinction between physicians and surgeons is nowhere to be deplored more than in connexion with surgery of the chest. In this field success often depends more on a correct appreciation of the "medical condition" of the patient, and of the time to operate, than on the actual operative technique. Since it is often difficult for surgeons, under conditions existing in this country at all events, to obtain the necessary "medical" experience, close co-operation with the physician is essential, and it is the physician who should accept the responsibility and insist upon due weight being given to his opinion.

Hence the book just produced by Sauerbruch and O'Shaugnessy is assured of an enthusiastic welcome. It is described as "a revised and abridged edition of Sauerbruch's *Die Chirurgie der Brustorgane*," but to most English-speaking readers it will open a wide field of experimental and clinical work that has stood the test of time. Professor Sauerbruch's pioneer work in chest surgery has always been carried out in a team by whom the associated medical problems were constantly being explored; and Mr. O'Shaugnessy's experimental work of more recent date has similarly found important clinical application in the operation of cardio-omentopexy.

The most valuable feature of the book is the logical presentation of the possibilities of active intervention in chest disease—a presentation that will appeal and be intelligible to the physician as well as the surgeon. The style is brief and to the point, yet the whole makes an interesting and connected account. The possibilities of surgery in the chest are well shown by the fact that almost half the book is concerned with surgery of the heart, pericardium, mediastinum, oesophagus, and diaphragm. Each condition described in the book is illustrated by case histories, often going back for several years (for instance, a thoracoplasty and a lobectomy each dating from before the war), thus meeting the frequent objection that such procedures are so new that the end-results cannot yet be correctly assessed. The need is stressed for placing exploratory thoracotomy—a safe procedure—on the same footing as exploratory laparotomy, if we are to discover more conditions in the chest at a stage when they are amenable to surgical treatment. It is good to find bronchiectasis discussed as a condition found in adults, with the addition of a section on its presence in children; for the common tendency to regard it as a disease of childhood has been responsible for its neglected recognition in adults. There are several unique features in the book—for instance, a tomogram of a lung abscess, a skiagram of a peptic ulcer of the oesophagus, a skiagram and a picture of a specimen of mediastinal emphysema, skiagrams and diagrams of mediastinal hernia, and the Graf diagrams of the mechanical effect of a

pleural effusion—all features to be found only in very specialized literature.

The general excellence of the book tends to emphasize several points for criticism. Only forty pages out of a total of 360 are allotted to the section on pulmonary tuberculosis. This may be useful in stressing the point that surgery of the chest is no longer synonymous with surgery of phthisis, but it does not take into account the fact that, owing to the high incidence of pulmonary tuberculosis, the surgical treatment of this disease remains the largest part of the thoracic surgeon's work. The discussion is too brief to assist the physician, and shows a conservative attitude that will rightly discourage reckless surgical interference by the inexperienced, but may at the same time cause many patients to be deprived of the benefits of surgical treatment by the experienced. In a comprehensive treatise of this kind it is disappointing, to say the least, to find also a very scanty account of endoscopy. Bronchoscopy, in particular, is an indispensable and (should be) a very frequent procedure in the diagnosis and treatment of chest disease, and it should have been very fully discussed. Minor points to which attention may be drawn are the absence of mention of pulmonary tuberculosis in the differential diagnosis of pulmonary abscess, and the inadequate insistence on early operation. The omission of dates after names of references should be corrected in another edition, since this book is written in a pronounced historical vein.

No praise is too high for the production of the volume. The format, the quality of the paper, the general lay-out, and the beautiful illustrations all add to the reader's enjoyment. Not the authors alone but also the publishers must be congratulated on this work, which should do much to popularize important practical advances in medical knowledge.

RADIOLOGY AND THE LAW

The Roentgenologist in Court. By S. W. Donaldson, A.B., M.D. (Pp. 230. 18s.) Springfield, Illinois; Baltimore, Maryland: Charles C. Thomas. London: Baillière, Tindall and Cox. 1937.

This volume stands out from a bewildering mass of American medical and semi-medical literature as a thoroughly sound work filling a large and yawning gap. Perhaps the first monograph on the legal position of the radiologist had to be written by an American, because in the United States radiologists are apparently subjected to a legal persecution quite inconceivable by their English colleagues. They are constantly dragged to the courts for mishaps of all kinds, and often have to pay damages for trivial burns which the most careful precautions could not have avoided. In America radiotherapy and electrical treatment are popular, and are practised by a number of persons who are perhaps not adequately qualified. Although in this country one seldom hears of an action for negligence against a radiologist, other legal problems nevertheless arise from time to time. One of these is the question of who owns the x-ray films which a radiologist makes as part of his examination of a paying patient sent him by a general practitioner, and, more difficult, who has the right in a particular case to call for their production in court. Dr. Donaldson has a chapter on the ownership of films, headed with the appropriate quotation from *As You Like It*: "An ill-favoured thing, sir, but mine own." In it he collects a large number of decisions given by the courts of different States, and quotes a judgment of the Michigan Supreme Court holding that, in the absence of agreement to the contrary, x-ray negatives are the property of the physician or surgeon who makes them in the course of his treatment.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 22 1938

BUG DESTRUCTION

The bed bug is not normally a vector of communicable disease, but everything else that can be said of it in its human relations is by way of dispraise. By means of its powerful beak it pierces the skin of man, raising a painful red blotch surrounded by papules. By means of a pair of glands situated in its thorax it diffuses a repulsive odour. It is a pest in houses, lying concealed by day in cracks and crevices and emerging at night to suck the blood of sleepers. The presence of bugs in dwellings, besides being vexatious to tenants, has also come to carry some suggestion of a social stigma, and quite a range of substances of varying degrees of activity has been employed from time to time for their extirpation. Turpentine and scalding water, corrosive sublimate and painters' blow-lamps, naphthalene and sulphur dioxide have all been applied without conspicuous success, and so recourse has been had, as a last resort, to gaseous hydrocyanic acid.

While fumigation with hydrocyanic acid has been found quite effective for the destruction of bugs, the method completely fails to conform to the requirement that a convenient disinfectant should not be unreasonably toxic to man, by attacking operators or dwellers in adjacent premises or by leaking out of stuffed furniture after the fumigation is over. When the acid is employed for killing rats in the holds of ships the whole procedure can be kept under strict control, but its routine use about people's homes for the destruction of insects, even granted that bugs are a pest and that all precautions are taken, as we believe they are, conveys to the mind a suggestion of incongruity between the risks taken and the results achieved. The report printed elsewhere in this issue (p. 160) is to the effect that the vapour of heavy naphtha may be found on extended trial to possess a bug-destroying power which is for practical purposes equal to that of hydrocyanic acid while at the same time non-toxic to man. The method recommended is to spray the naphtha on the surfaces to be disinfected and also on sheets of Egyptian cotton hung on frames of electrical conduit tubing three inches from the walls, with a view to producing a concentration of naphtha vapour in the air of the room. The room is then sealed and kept sealed

for twenty-four hours. Just before sealing up the room a clockwork-driven delayed-action naphtha sprinkler is placed in position and set to deliver a reinforcing charge of naphtha from nine to eleven hours later. This is done in order to ensure that naphtha vapour remains in the air in lethal concentration. When the room is unsealed all bugs should be dead. Lethal concentrations of naphtha for bugs are from 0.15 per cent. upwards, with twenty-four hours' exposure. It is important that the room temperature should not fall below 50° F., and preferable that it should be 60° F. or over. Owing to the rapid escape of heat from houses, rooms for disinfection in winter should be raised to 80° F. before the process begins. As the flash point of the naphtha is 105° F. no naked lights or tobacco smoking can be permitted. The only instance of disability among the workmen employed on the tests was one case of irritation of the skin of the hand, which readily yielded to lanoline. With suitable modifications the method can be applied to empty or furnished rooms or vans containing furniture.

On weighing up the results of the tests which have been carried out the impression is distinctly favourable to the tentative claims made on behalf of heavy naphtha. The reporters have rendered a useful service by their work with the substance. If bugs can be killed with ease and precision by its means there will be no need for operators or others to incur the major hazard of hydrocyanic acid.

DIETETIC THERAPEUTICS

At the present time the subject of dietetics is front-page news. That is unfortunate for its consideration in an atmosphere of scientific calm. There would appear to be two main reasons for this popular interest—one good, the other bad. The good one is that our social conscience is rightly stirred by the question of unemployment and the risks of consequent malnutrition; there is a strong desire to see that the available resources are wisely applied. The bad reason is symptomatic of the widespread neurosis of the present day. Neurosis is generally characterized by a regression to more primitive modes of thought, and for the infantile mind the working of its alimentary canal is the prime interest—an interest which, indeed, the mother and nurse foster. An anxiety state therefore generally involves a certain fussiness about food. Such a patient seeketh after a prescribed diet and will not be comforted without one, thereby often falling a not unwilling victim to cranks.

The end of the nineteenth century saw the quantitative aspect of diet firmly established: the role

MOTOR FUNCTIONS OF THE ALIMENTARY TRACT

Normale und Pathologische Physiologie der Bewegungsvorgänge im Gesamten Verdauungskanal. Zweiter Teil, Klinik, Pharmakologie. By Professor Dr. Med. Werner Catel. (Pp. 298; 123 figures. M. 15; GM. 16.50.) Leipzig: Georg Thieme. 1937.

Dr. Werner Catel, who is director of the University Children's Clinic at Leipzig, has continued his study of the motor functions of the alimentary canal, and in the second volume of his work on the normal and pathological physiology of the motor functions of the whole alimentary tract he deals with clinical and pharmacological considerations. The subject is covered in a thorough manner, beginning with the physiology of sucking, of chewing, and of swallowing, and then going on to consider the stomach and intestines in great detail. Radiological studies are made use of in all sections, and the later portions of the book, which deal with pharmacology, describe the effects of selected drugs in series of animal and human experiments. References to the literature are given in some detail, and the whole monograph can be recommended to those whose special interest lies in the alimentary tract in health and disease. The author's special clinical interest lies in the field of paediatrics, but his appointments apparently also include a general out-patient clinic, so that adults also come under consideration, and the clinical basis of the study is a wide one.

Notes on Books

The forty-fifth edition of the *Annual Charities Register and Digest* has been published by the Charity Organization Society. The subtitle of this valuable reference book describes it as a "classified register of charities in or available for the Metropolis," but in fact the scope is much more comprehensive. Details are given of more than 2,700 institutions and societies, and the index, as usual, is particularly full. There is also a statistical chapter on the finance of the social services, voluntary and official, and a list of addresses of social case-work societies all over the world. Copies of the 1938 edition of this indispensable directory of charities and public institutions for the service of persons in trouble or need can be obtained from the Charity Organization Society, Denison House, Vauxhall Bridge Road, S.W.1 (cash price 8s. 6d. in the United Kingdom).

The continued popularity of *Black's Medical Dictionary* has called for a fourteenth edition, which completes the printing of 100,000 copies since its first appearance in 1906. The author, Dr. J. D. COMRIE, has taken full advantage of this opportunity of bringing the book thoroughly up to date in regard to recent medical advances. It now comprises more than a thousand pages of text and five hundred simple illustrations. It is published by A. and C. Black at 18s.

The *1937 Year Book of General Medicine* (The Year Book Publishers, Chicago, and H. K. Lewis, London, 12s. 6d.), one of the practical medicine annuals, now in their thirty-seventh year, is, like its immediate predecessor, divided into five parts, devoted respectively to infectious diseases, by George F. Dick; diseases of the chest excepting the heart, by Lawrason Brown; diseases of the blood and blood-forming organs and diseases of the kidney, by George R. Minot and William B. Castle; diseases of the heart and blood vessels, by William D. Stroud; and diseases of the digestive system and metabolism, by George B. Eusterman. Among the subjects receiving special attention are arthritis, immunization against diph-

theria and influenza, prontosil therapy, air-conditioning, silicosis, pneumonia, carcinoma of the lung, collapse treatment of pulmonary tuberculosis, hypochromic and haemolytic anaemias, various types of leukaemia, hypertension, coronary thrombosis, electrocardiography, peptic ulcer, and diabetes.

Food Tables, by V. H. MOTTRAM and ELLEN M. RADLOFF (Arnold, 5s.), "is intended to fill a gap in the equipment of the dietitian and to supply a set of tables collected from authoritative sources of the composition of the most used of British foodstuffs." It is based on the most up-to-date analyses, in which the content of mineral substances has been accurately estimated and in which foods have been analysed as they are served at table. In all cases analyses are expressed in terms of portions of 100 grammes, 1 oz., 4 oz., and 1 lb., and figures are given where available not only for protein, fat, carbohydrate, and total calories, but also for calcium, phosphorus, and iron. In many cases figures are also given for waste, roughage, non-phytin phosphorus, and titratable acidity. The authors have done a very useful bit of work, and this little book will be invaluable to all who have to calculate and dispense diets.

The scope of *Studies on the Bacterial Flora of the Respiratory Tract in Acute and Chronic Bronchitis, Bronchial Asthma and Lung Gangrene*, by SVERRE DICK HENRIKSEN (Oslo: Jacob Dybwad, 1937, 18 Kr.), is indicated in the title of the monograph. It contains the results of investigations carried out over a period of four years into hitherto little studied problems at the bacteriological laboratory of the Norwegian Army. The author was able to demonstrate that the vast majority of cases of acute bronchitis are caused by a pure infection with *Hemophilus influenzae*, pneumococci, or haemolytic streptococci, or by a mixed infection with two of these organisms. The results in the other conditions studied were less clear-cut, but are of interest. The book is written in better English than most publications from Scandinavian countries.

That a third edition of Dr. R. RIVOIRE'S *Les Acquisitions Nouvelles de l'Endocrinologie* (Masson, 45 fr.) has been called for so speedily is not surprising, for it is very attractive both in matter and manner. The author ingeniously compares the newer phases of his subject to the transition from a pastoral to an agricultural state—mere surface grazing is no longer enough; we are ploughing deeper. He expresses legitimate satisfaction that several of his earlier hypotheses have been subsequently confirmed by recent observations. He now adds another theory—that myasthenia gravis is due to a thymic adenoma and is characterized by an excess of sodium and a deficiency of potassium in the blood—the precise opposite of the conditions obtaining in Addison's disease. Some interesting observations are recorded in support of this view. The chapters on the thyroid and pineal are new, and the whole book has been revised so as to bring it thoroughly up to date.

The International Congress of the Union of Therapeutics held its first meeting under the presidency of Professor. Emile Buerger at Berne last May, and the bound volume of proceedings (624 pages in length) has been published by Medizinischer Verlag Hans Huber, Berne (price RM. 14.40). Copies may also be obtained from Masson et Cie, 120, Boulevard Saint-Germain, Paris, VIe (price 24 francs).

The monograph on *Castellani's Bronchospirochaetosis* (Palermo: L. Salpietra, lire 18), containing a brief introduction by Sir ALDO CASTELLANI himself, gives a concise and lucid account of a condition first described in 1905. Nineteen illustrative cases are recorded in patients aged from 20 to 61. An international bibliography of 142 references is appended.

so-called recovery stage during which spontaneous return of function is seen in muscles previously weak or completely paralysed. A valuable contribution on this subject from the Royal National Orthopaedic Hospital, London, appears in our current issue at page 164. In this article Mr. N. M. Harry shows that in a series of thirty-six cases treated by the orthodox methods of rest, splinting, and a carefully graded system of re-education striking and rapid recovery of muscle function occurred only during the first year, and more especially during the first six months. The system of muscle-charting employed at the Royal National Orthopaedic Hospital is admirable in its simplicity, and it is only upon such data that authoritative statements on recovery in poliomyelitis can ever be based. Similar criteria have been used by the Council of Inquiry composed of distinguished consultants in Sydney, who have recently reported¹ to the Minister of Health of New South Wales on the results of Sister Kenny's treatment at the Royal North Shore Hospital. The small series of cases under review were all patients with poliomyelitis of some years' standing. The council expressed the opinion that although there was considerable improvement in several cases recovery from paralysis had not taken place at a greater rate or to a greater extent than would be expected under orthodox methods of treatment. Furthermore, in its opinion Sister Kenny's treatment did not embody any new general principle. At the same time the council recommended that the work of the Elizabeth Kenny clinics should be incorporated in a comprehensive scheme for the treatment, education, and rehabilitation of the cripple in New South Wales. An inspection of Sister Kenny's treatment at work shows that it embodies many re-educative manœuvres which could be used with advantage in centres where poliomyelitis is treated on orthodox lines. As a distinct system of treatment the method is obviously still *sub judice*, and a final opinion must be withheld until a larger series of fully documented cases have been examined and reported on by an impartial committee of experts.

OPTO-CHIASMIC ARACHNOIDITIS

The "pathology of the living" has added to the pituitary syndrome of bitemporal hemianopia a new clinical fact—namely, that the syndrome is not necessarily of pituitary origin. As neurological surgeons have been exploring the pituitary region with greater frequency they have not uncommonly found that an operation undertaken in the full confidence of finding a pituitary tumour revealed no such condition. It has of course been recognized for some time that lesions in the pituitary region are of sellar and suprasellar origin. What is new, however, is that neurological surgeons have come to regard a localized meningitis at the chiasma as a distinct clinical entity. Earlier observers when confronted with this localized inflammation assumed that it was either a reaction round a tumour or a cyst formation of obscure origin. As early as 1924 Horrax, when analysing cases in Cushing's

clinic, found thirty-three in which a cerebral tumour was simulated by arachnoidal cysts, and drew attention to one particular form in which the arachnoiditis was situated at the chiasma. Gordon Holmes in 1929 reported two cases operated upon successfully so far as vision was concerned, in one of which, treated by Percy Sargent, the condition dated back to 1919. The clear recognition that a clinical entity was being dealt with, and that it was indeed a localized basal arachnoiditis, not a secondary reaction to adjacent tumours, came with almost simultaneous papers in 1931 of Heuer and Vail in France and Craig and Lillie in the U.S.A. Since then a literature has grown up on the subject, and a valuable review of it is contained in a monograph by J. Bollack, M. David, and Puech,² recently published by the French Ophthalmological Society. An interesting clinical picture emerges from their detailed study of the sixty-three cases they have collected from the literature and the sixty-six they have studied personally. That the condition is no rarity is clear from the fact that of the 254 transfrontal explorations undertaken at Dr. Clovis Vincent's clinic at the Pitié during the past six years no less than seventy-one, or 27 per cent., proved to be cases of arachnoiditis, almost as frequent as pituitary adenoma, of which seventy-four cases were found. The commonest form of arachnoiditis is of the adhesive type, the adhesions ranging from fine strands to massive sheets of exudate sometimes containing calcareous flakes. A serous type with cyst formation is not infrequent, while the least common type is one in which there is minimal exudate but grey, unhealthy-looking optic nerves and chiasma. The optic nerves and the chiasma may themselves appear variously, ranging from engorgement and oedema to atrophy with fibrosis, while in some cases there are no changes at all. There is no predilection as regards age, though at different ages different aetiological factors play a dominant part. The commonest exciting factor is sepsis in the mouth and sinuses, and meningitis—syphilitic, tuberculous, or colibacillary—is not infrequent. The route of infection may be haematogenous, as is probably most often the case, or the arachnoiditis may be caused by a contiguous spread of infection from an infected sphenoidal sinus. Trauma appears to have played an undoubted part in some of the cases. The fully developed pituitary syndrome, so far as ocular manifestations are concerned, may be present, but sometimes signs suggestive of unilateral or bilateral retrobulbar neuritis with the corresponding subjective findings may be the only features. The field defects may be of a bizarre distribution and not at all of the type of more or less frank bitemporal hemianopia. An important consideration is the fact that while classical signs of cerebral tumour may be present there are generally no neurological findings of any significance, though there may be such unusual features as diabetes, disturbances of the adiposogenitalis type, and indications of basal meningitis elsewhere. A capricious progression in symptoms, with the discovery of aetiological factors, suggests a diagnosis of this condition. As the authors put it, in a schematic way

¹ *Med. J. Austral.*, 1937, 2, 888.

² *Les Arachnoïdites opto-chiasmatiques*. Paris: Masson et Cie, 1937.

of each foodstuff, their minimum and optimum quantities, the total calorie requirement—all these things were generally agreed. It was known, however, that a mixture of chemically pure proteins, carbohydrates, and fat, even with the addition of the salts extracted from cow's milk, would not sustain life. The only explanation then available was that some at least of the salts must be present in organic combinations such as are found in animal or vegetable foods. Then early in this century came the realization of the great importance of certain qualitative as opposed to mere quantitative factors. When Sir Frederick Gowland Hopkins found that the addition of a few cubic centimetres of milk to the carefully purified diet of rats made all the difference between ability and failure to grow, a new era in dietetics dawned. True the influence of lime juice (or, better, lemon juice) in the prevention of scurvy was known, as was the effect of polishing rice in inducing beriberi; but now the whole question of deficiency diseases opened up. Looking back, it is perhaps curious that this new idea developed rather slowly. It was the consequences of food restriction during and after the war which focused attention on the subject, though Casimir Funk had labelled these accessory food factors "vitamines" before the outbreak of hostilities had necessitated his return to his native land. He was under the impression that these factors were amines, but, this proving incorrect, the non-committal name of vitamins was substituted. Yet even in 1918 controversy still raged as to whether rickets was a disease of diet or of the dark.

It is this retrospective spirit that adds point to Dr. Leslie Cole's address, "Diet in General Practice," printed at page 157 this week. It may be safely asserted that the ordinary mixed diet of the comfortably situated person is not likely to suffer in quality; there will be no lack of accessory food factors. The more probable risk is that the diet may be excessive in quantity. Danger as to quality arises, however, under two conditions—where the total intake is grossly reduced by poverty, and where it is greatly limited as to quantity and variety by disease. The danger of the former condition is now realized, though the issues have been to some extent obscured by political controversy; it is the risks in the latter circumstances to which Dr. Cole usefully calls attention. The study of minor degrees of vitamin deficiency has now reached a more accurate stage by the introduction of quantitative methods of estimating this lack. Thus we have the dark adaptation test for vitamin A (M. K. Maitra and Leslie Harris),¹ the urine saturation test for vitamins B₁ and C, and the

blood phosphatase test for vitamin D. Particularly has an unsuspected deficiency in vitamin C been revealed by the test dose of ascorbic acid, which is excreted by those already taking a sufficient supply of the vitamin but retained by those previously inadequately supplied. Recently in our columns Lazarus² reported an investigation of fifteen cases of haematemesis and melaena, in thirteen of which a deficiency of vitamin C was revealed; this was of a severe degree in seven of the cases. The addition of such things as orange juice, marmite, and cod-liver oil to the diet of these patients has been recommended and is a rational measure. Nor is this the only instance: in rheumatoid arthritis a similar vitamin deficiency has been observed. Evidently we are entering on a new phase of dietetic therapeutics, and one which is based not merely on general impressions and guesswork but on accurate observations quantitatively controlled.

TREATMENT OF ANTERIOR POLIOMYELITIS

Much interest has been aroused lately by reports which have reached this country of the results achieved in Australia by what is known as the Sister Kenny system of treating anterior poliomyelitis. In this issue of the *Journal* (p. 168) Dr. F. H. Mills describes this treatment, expounds the principles on which he believes it to be based, and offers certain criticisms of the methods of treatment which have for many years been in vogue in most countries. The main criticisms of the orthodox routine are that complete rest and immobilization and the use of splints induce trophic changes, minor deformities, and stiffness of joints; and that re-education is delayed far too long, the conventional technique being crude, apt to cause fatigue and encourage trick movements, and therefore ineffective in restoring the maximum recovery of muscle. In Sister Kenny's method movements of the limb are deliberately carried out in the pyrexial stage for the relief of pain, assisted by some form of local heat. No splints are used, the paralysed limbs are sprayed with hot and cold water (the patient being in a bath), and at the end of the first week what is described as a finely graded system of re-education is begun. So far only thirty-five patients in the early stage have been treated in Australia, and 1,400 chronic cases have been treated on similar lines, with, it is claimed, much improvement. Sister Kenny's technique is now being tested in this country at Queen Mary's Hospital, Carshalton (L.C.C.), where a ward has been set apart for what is undoubtedly a reasonable and most interesting clinical experiment. The ultimate evaluation of what at first sight seems to be a revolutionary departure from accepted routine will depend on a careful study of a series of cases which have been accurately documented from the beginning. There has been much inexact writing about recovery in poliomyelitis, and particularly about the limits of the

² *British Medical Journal*, 1937, 2, 1011.

for even to-day few tuberculosis dispensaries fulfil in practice the wide vision of Philip. Some of the historical details, particularly those connected with Koch, are fascinating, and should be read by every student of tuberculosis. It is inevitable that there should be much repetition of material in the papers; but those who might complain should remember that it was this very repetition, this insistence on bringing the same points forward, that did so much to awaken public consciousness to the gravity of the problem and led to the development of a scheme of control which, however faulty in its application, is basically the soundest means so far evolved to combat the disease.

THE ACTION OF THE CORONARY ARTERIES

Physiologists differ widely on the question of the control and mode of action of the coronary arteries. Whenever one school attributes a vasodilator influence to the sympathetic another considers the control of these vessels similar to that of the peripheral arterial system. In a recent paper Champy and Jacques-Louvel¹ draw attention to the need for distinguishing between true vasodilatation and vasodistension. Working with the frog's mesentery, the authors observed the effects of a drop of adrenaline (1/1,000) on the calibre of the vessels: all the vessels—arteries, veins, capillaries—responded with an unequivocal constriction, the veins, however, showing less response than the arteries. Repetition of this experiment, with the root of the mesentery clamped so as to obstruct the venous return, led to the finding that, while the arteries constricted when treated with the adrenaline, the veins dilated rapidly. Such an effect is due not to a dilator action of adrenaline on the veins but to the inability of the constrictor action on the veins to resist the haemodynamic force exerted by the contracted arterial musculature. Such a mechanism is proposed by the authors to explain the vascular engorgement produced in certain vessels—for example, the pulmonary and intestinal vessels—by an intravenous injection of adrenaline. It is to be noted that in almost all cases in which intravenous adrenaline gives rise to vasodilatation the effect of local application of the same agent is vasoconstriction. Arguing on these lines, the question is asked whether the usually accepted effect of adrenaline in dilating the coronary vessels cannot be explained in a similar way. In an investigation of this the coronary arteries of a horse's heart were studied immediately after death. Segments of the coronary arteries were attached to a graduated reservoir containing an appropriate perfusion fluid, and the rate of flow through the segment at constant temperature and pressure was measured with and without the addition of adrenaline. The method used was admittedly crude, but the results obtained were sufficiently clear-cut and uniform to warrant conclusions. It was first of all demonstrated that adrenaline had no effect on the coronary segments from the aorta to the bifurcations.

The interventricular coronary segments, however, were definitely sensitive to adrenaline, thus exhibiting an autochthonous vasomotor system, which was still sensitive an hour after the death of the animal. So pronounced a difference in reaction led the authors to attempt an explanation on structural grounds. Histological study showed that the coronary arteries from their origin to their bifurcation are similar in structure to the aorta—that is, they consist mainly of elastic tissue and hence would not be expected to respond to adrenaline. The interventricular coronary branches are, on the other hand, of the muscular type of vessel, and hence much more prone to changes in calibre. Besides circular muscular fibres the interventricular branches possess bundles of longitudinal fibres, the latter being situated near the periphery of the vessels while the former are subendothelial. The longitudinal fibres are conspicuous in the horse, but have also been described in man and in the guinea-pig. Thus these branches of the coronary vessels may be constricted by the circular fibres and dilated by the longitudinal fibres, and it seemed probable that the effect of adrenaline would depend upon the degree to which this agent came into contact with the relevant fibres. On following this up the authors found that impregnation of the walls of these coronary segments with adrenaline led to vasodilatation. The conclusion is, therefore, that the constriction observed on perfusing adrenaline through the lumen of the vessel is brought about by the circular fibres, to which the active agent can penetrate while the longitudinal fibres remain more or less unaffected. The mechanism of control of the coronary vessels appears thus to be twofold—mechanical in the parts mainly composed of elastic tissue, and nervous in the parts composed of circular and longitudinal muscular tissue. The therapeutic possibility of adrenaline in cardiac infarction arises, and indeed some success has been reported by Donzelot. Justification for this lies in the fact that the circular fibres possess relatively poor contractile power compared with that of the longitudinal fibres. The hypothesis that vascular spasm is responsible for certain cases of coronary insufficiency is also called in question, and it is suggested that they are due rather to insufficiency of the dilator mechanism.

NEW YORK HEALTH RECORDS

In his report on the health of New York City during 1937 the Health Commissioner, Dr. John L. Rice, announces the lowest infant mortality rate, the lowest death rate from typhoid fever, the lowest tuberculosis death rate, and the lowest proportion of deaths of mothers in childbirth. All four are the best records ever attained in the history of the city. For the reduction in the maternal death rate Dr. Rice gives credit to the New York Academy of Medicine and the county medical societies, which have done effective work in this field. With a total of 101,988 births during the year and 77,466 deaths, there was an excess of 24,522 births over deaths. During the past ten years there has been a constant decline in the birth rate; now for the first

¹ *Presse méd.*, 1937, 45, 857.

it may be said that the affection gives hybrid symptoms of a tumour together with inflammatory reactions along the optochiasmic tracts. What is of particular import is the fact that operations to free the optic nerves and chiasma from the adhesions give favourable results in a good many cases, though in some the operation may have to be repeated. In assessing prognosis age is an important factor. The arachnoiditis of childhood¹ is generally due to a localized meningitis. In the aged, however, the prognosis is poor, since in some cases the reaction is secondary to lesions of cerebral vessels. This monograph, with its careful documentation, opens a new chapter in the study of lesions of the chiasma, a structure which Cushing has aptly described as the cross-road at which the ophthalmologist, otologist, endocrinologist, and neurological surgeon meet. To the ophthalmologist it is of particular interest in helping to clear up obscure points in the symptomatology and aetiology of optic atrophy, and in enlarging the limited field where treatment of optic atrophy is helpful. This new conception has, for one thing, made the puzzle of retrobulbar neuritis of obscure origin a little less formidable.

ARTIFICIAL LIGHTING AND THE WORK OF WEAVERS

There can be very few industrial occupations in which adequate lighting is more important than in weaving, and Report No. 81 of the Industrial Health Research Board, by H. C. Weston,¹ which deals with the effects of various conditions of artificial lighting on the performance of weavers, is likely to be of considerable practical value. In this country the usual method of illumination in weaving sheds is by means of lights fixed vertically above the looms, but an investigation made in Germany appears to indicate that it is better to direct the light across the looms from the side. In order to test the two methods a group of six night-shift weavers were kept under observation for successive periods of five weeks at a time, and their output of cloth was compared with that of a corresponding group of day-shift weavers operating the same looms. The results obtained showed that when the system of overhead localized general lighting which is customarily employed in weaving sheds was doubled in intensity, the personal efficiency of the weavers in mending thread breakages and doing other hand work increased no less than 24 per cent., while there was a substantial improvement in the quality of the work done. These improvements were surprising in view of the fact that the illumination previously used had apparently caused no dissatisfaction in the weavers. A still further increase in illumination had no better effect than its doubling, and the other systems of lighting tried, whether localized or lateral, did not give such good results as the one mentioned. It is to be remembered that the weaver has constantly to be on the alert, not only to mend breakages in warp threads but to note when the weft threads are running low and fresh shuttles are required.

If the cloth is a fancy one several shuttles are used, each containing weft of a different colour. As the weaver has to superintend two looms they often need attention at the same time, and his task seems a very trying one. Moreover, he is often subject to adverse environmental conditions such as high temperature and a humid atmosphere.

A PIONEER IN TUBERCULOSIS

Last year we paid our tribute¹ to Sir Robert Philip on the occasion of the fiftieth anniversary of the foundation in Edinburgh of the first tuberculosis dispensary in the world. Few would question Philip's claim to a place among the outstanding names connected with tuberculosis, but perhaps not many are familiar with the details of the part played by him in developing an interest in the control of the disease in this country and abroad and in guiding this interest into practical channels. The publication of a volume² containing twenty-four of his papers and addresses written or delivered in this country and elsewhere between 1898 and 1934 should enable everyone fully to appreciate his pioneer work. So much of what he said in the past holds good to-day, so little has been contradicted by later events, that at times, in view of the scanty experimental and pathological evidence then available, one feels like ascribing to him a prophetic sense. Sir Robert Philip would probably himself no longer emphasize the value of "aerotherapy" at the expense of rest, insist on the role of the lymphatic system in the dissemination of tuberculosis, or claim that the pharynx is a common portal of entry for the bacillus. On the other hand, how strongly do we feel like applauding his reiteration that tuberculosis must invariably be regarded as a general disease, his arguments in favour of having sanatoria built near towns, or the wise conclusion—of increasing importance—that well-equipped laboratories "in close relationship to tuberculous clinical material" are "a primary need"! His faith in tuberculin as a mode of treatment makes one wonder whether its almost total rejection in therapy has not been too hasty. And though we might not agree with "distrust in its value I have found most commonly expressed in loudest terms by those whose acquaintance with tuberculosis is limited and whose knowledge of the actual treatment is fragmentary or second-hand," the need for a re-trial of tuberculin therapy by competent workers should perhaps be considered. The history of the development of tuberculosis control as depicted in these pages shows well its pendulum swings. The sanatorium movement is a good example: the long delay in recognizing the value of this institution was followed by an over-enthusiasm which has given way to a more reasonable appreciation of its true function. But the pendulum still moves, and there is a danger of fresh air and good food being too thoroughly ousted in favour of major surgical procedures. On the other hand, the dispensary movement still tends to emulate the tortoise.

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

TREATMENT OF WOUNDS—II

BY

W. H. OGILVIE, F.R.C.S.

(This is the second of two articles on the treatment of wounds, of which the first appeared last week at page 132.)

Dressings

A dressing is no magic talisman; it is the tissues themselves that do the healing. The dressing serves two purposes only: to prevent fresh infection and to afford mechanical protection to the wound. Frequent changes are therefore valueless and may be harmful. The dressing should only be changed when it has ceased to perform the above functions—that is, when it is soaked or displaced—or when access to the wound is required for the removal of stitches or drains. The daily dressing—which was formerly a ritual—merely delays healing by damaging the wound edges and the freshly growing cells in skin and granulation tissue. Gauze soaked in an antiseptic has little advantage over sterile gauze, beyond giving a further guarantee that its sterility is a matter of fact rather than faith. Antiseptics are at their best *in vitro* and on blotter circulars. Few bacteria are killed by their action in a wound, and then only those in the discharge, the defeated enemy, of no further fighting value, escaping in the rout; the shock troops, the organisms multiplying in the tissues, are unharmed and possibly favoured by the application of chemical agents, and can only be vanquished by the action of the tissues.

A respect for natural defence mechanisms dominates the modern attitude towards dressings, which demands rest and non-interference, combined in the presence of sepsis with free drainage. Vaseline, which is entirely innocuous and easily sterilized, is an excellent medium both for dressing and for drainage. A wide-mesh net of vaseline gauze is a valuable surface dressing where a large flap of skin has been torn back and sewn into position again. The vaseline net keeps the edges secure and protects them from injury, while discharge can escape through the meshes and outer dressings can be applied to soak up fluids and distribute pressure on the flap without disturbing the healing edge. Such a vaseline net with eight meshes to the inch is obtainable readily sterilized as "tulle gras lumière." Ordinary gauze impregnated with sterile vaseline is used for the drainage of wounds that have become infected. The gauze may be packed loosely into all parts of the wound, and heaped up on its surface. Wounds so treated need dressing at infrequent intervals only, and the scar after they have healed is remarkably supple.

Tannic acid (2.5 per cent. solution), the preparation widely used in the treatment of burns, is an excellent dressing for clean superficial wounds inflicted with a sharp knife or razor, particularly those in which part of the tip of a finger has been shaved off. The tannic acid forms a firm coagulum that remains as a protective scab till the wound underneath has epithelialized completely.

Antiphlogistine provides a useful first dressing for those large and dirty grazes on the shins, knee, or forehead, which are often the result of motor accidents or falls on the playground. The clay poultice is most efficient in removing collections of grit and debris from the deeper

layers of the skin where they have become embedded, and where, if not removed early, they will remain as disfiguring "tattoo marks."

Drains and Sutures

A drained wound should usually be left alone for forty-eight hours. If at the end of this time the appearance of the wound and its surroundings indicates that there is no infection the drain should be removed, if there is doubt it may be shortened and removed on the following day. Where infection has taken place the drain must be left till such infection has been overcome. Nothing is more harmful than to remove drains and reinsert them after boiling, to twist them round, or replace them with others. The original drain has its own bed; a new one has to make a fresh bed by killing tissues. In the abdomen we are anxious to remove drains early, but in soft parts it is better to leave them too long than to remove them too soon. Premature removal may mean the accumulation of septic material in the depths of the wound and the formation of an abscess, while late removal implies no more than a few days' delay in healing.

In a wound that has been brought together without tension the cut is completely epithelialized in four days. Stitches that are approximators only should be removed at this stage, while those that take or relieve tension should be left in for eight or ten days. After ten days stitches merely cut out and serve no useful purpose. If tension on the edge must still be combated this is best done by strips of elastoplast fixed outside the wound, and tied with tapes over the dressing.

Treatment of Sepsis

Sepsis is rarely encountered in wounds that have been excised and packed open at the start. It is seen in the untreated wound brought late to the doctor, or in those wounds that have been closed without, or with insufficient, drainage. The treatment of sepsis as a late complication is by immobilization and free drainage. Immobilization is of paramount importance, and should be complete and uninterrupted. This usually means enforced recumbency, the application of a splint, and the avoidance of frequent dressing. In a septic wound of the arm or leg it is an excellent plan to sling the whole limb in a Thomas's splint from an overhead frame. Two alternative methods of dressing, both of which allow free drainage without interference, may be recommended for septic wounds—namely, the vaseline pack, and intermittent irrigation with Carrel tubes. The first is suitable for the open wound of simple shape, the second for one with pockets or underhung flaps. In either case the pack or tubes are preferably put in under gas anaesthesia.

After the stitches have been removed and the wound has been opened up, vaseline gauze is tucked lightly into its recesses and heaped over the mouth and edges, and an abundant dressing of wool is placed over the part to take up discharge. Unless there is any indication in the condition of the patient or of the limb outside the bandages that progress is not satisfactory, this dressing is left unchanged for a week at any rate, or for such longer period as the smell of the dressings will allow. The cavity closes rapidly round the vaseline gauze, the healthy granulation tissue pushing out the plugs, and after two changes it is

time the rate is higher than it was in the preceding year. Dr. Rice suggests that the change resulted from the better economic conditions prevailing during the greater part of 1937. The 77,466 deaths represent a death rate of 10.4 per 1,000 of population, "a remarkably low rate for a large city like New York with its housing problems, its many foreign born and with so many persons unemployed. We would have made even a better showing had it not been for a sharp outbreak of epidemic influenza beginning at Christmas, 1936, and lasting throughout January of 1937. This outbreak cost over 1,500 lives, a loss more than double the deaths caused by measles, whooping-cough, scarlet fever, diphtheria, and typhoid fever all combined." Commenting on the 6,505 deaths from pneumonia during the year, Commissioner Rice expresses the hope that the pneumonia control programme recently inaugurated by the Department of Health will soon begin to show results in a reduction of the death rate from this disease. "Early diagnosis and prompt use of the proper serum after the type of pneumonia germ has been determined will undoubtedly save many lives. Our laboratory has effective serums available for five or six of the most prevalent types, and these account for about four-fifths of all the pneumonias now occurring in the city. We have typing stations in each of the boroughs, and the one in Manhattan gives a 24-hour service, including Sundays and holidays." A feature of the Department's activities was the development of the campaign against syphilis. The close of the year saw twenty health districts organized, each with a full-time health officer in charge; nine of the centres are housed in new buildings specially planned to provide complete health services for the people of the district. The Department of Health now has 385 typhoid carriers under supervision. They report to the Department twice a year and are given instructions regarding the precautions to be taken in order to prevent the infection of others. They are not permitted to engage in food-handling occupations. Thanks to the sanitary supervision and chlorination of the municipal water supply, and the pasteurization of all milk sold in the city, New York has had no water-borne or milk-borne outbreaks of typhoid fever during the past quarter of a century.

HOSPITALS FOR CIVILIAN CASUALTIES IN AIR RAIDS

As was indicated in the course of proceedings upon the Air Raid Precautions Bill, the Government has for some time had under consideration the arrangements to be made for civilian casualties in the event of an emergency. Local authorities are already making in their air raid precautions schemes provision for the establishment of clearing hospitals, and it has now been decided that, with a view to making the fullest use of the existing facilities and extending them if necessary, a complete survey of the hospital accommodation of the country (including any earmarked as clearing hospitals) should be carried out. The survey will be undertaken in England and Wales by the Minister of

Health, and in Scotland by the Department of Health for Scotland. In England it will be made through the agency of a staff composed of the general inspectors of the Ministry and certain selected medical officers. In Wales it will be made by the Welsh Board of Health. These officers have been instructed in the first instance to confer with medical officers of health concerned and with the leading representatives of the voluntary and other hospitals. So far as the provision of accommodation in or on the sites of mental hospitals and mental deficiency institutions is involved, the survey will be undertaken in England and Wales by the Board of Control, and in Scotland by the General Board of Control for Scotland.

IRISH DISHES

Miss Florence Irwin has brought together a number of dishes designed "both to nourish and to please"—as Mr. St. John Ervine says of them in his entertaining preface to the book.¹ In it there is also much that is instructive. For here the non-Hibernian cook may learn—learning often sorely needed—how to treat the potato with the culinary consideration it deserves. In vain may expert committees of the League vaunt the virtues of the vegetable, in vain advise its substitution for white flour—that frequent disturber of gastrointestinal peace—so long as there are cooks who make of this goodly tuber a soapy sacrifice. Miss Irwin tells of ways in which it may be rightly cooked and served—jacketed and unjacketed—of potato-cake and potato-pudding, of potato-oaten farls, and "champ"; chive, nettle, parsley, pea, and scallion. She tells, too, of right uses to which oatmeal and wheatmeal may be put and of other things showing how "protective foods" may be combined to form delicious dishes. Poets, politicians, orators, and saints, doctors, divines, and Presidents of the United States are among Erin's gifts to the English-speaking race: these, and the staple breakfast dish of Britishers where'er the sun doth his successive journeys run. Who knows what the far-flung Empire owes to the union of the bacon with the egg? Yet, as Miss Irwin tells us, the conjunction came about "by the grace of God and the irregular proclivities of a lazy hen." Champ, stirabout, and brotchan roy; broth, brawn, and real Irish stew; durgan, flummery, and sowans—these are among the dishes of which, we feel, nutrition experts would approve; but "soda-bread" we think they would eschew. "Synthetic flour, synthetic fruit, synthetic juices, and synthetic bread must one day result in synthetic people. It is to avoid that calamity that this book is published, and I wish, indeed, that it may fulfil its holy purpose." So says St. John Ervine—and we endorse this hope.

Professor C. Regaud has retired from his position as director of the Radium Institute of Paris and has been succeeded by Dr. Antoine Lacassagne.

¹ *Irish Country Recipes*. Compiled by Florence Irwin. Belfast: The Northern Whig, Ltd. (2s. 6d.)

divided it may be accepted that the ulnar vessels are also cut, and these should be isolated and ligatured at both ends before the nerve is approached. Nerve suture depends for its success on there being a minimum amount of scar tissue across the suture line. The two ends must be healthy, and must be approximated by interrupted sutures which pick up only the perineurium, and which bring the two ends together without rotation, without separation, yet without compression. The line of suture must not be involved in any neighbouring repair, or in the reaction to infection.

If the ends of the nerve are seen to be clean-cut and if the surrounding injury is slight, repair may be carried out at once. The cut surfaces, if at all ragged, may be trimmed by a single cut of a sharp razor blade on a cork laid under them, but any wide clearing or resection should not be attempted. After this trimming four interrupted sutures of the finest intestinal catgut are passed through the sheath alone at the four quadrants, and pulled so as to approximate the ends very accurately before they are tied and cut. After the nerve has been thus repaired the line of suture should be shut off from any area of adjacent repair by stitching a flap of healthy tissue around it before the wound is closed. When there is much laceration, when repair is undertaken after twelve hours, or when the wound is in any way infected, the injured nerve should be left untouched, to be repaired later by secondary suture when other structures have soundly healed.

Wounds in the Neighbourhood of Joints

Penetrating wounds of joints demand consideration in a separate article. Very often, however, a wound is seen to be near a joint, but it is uncertain whether actual penetration has or has not taken place. In such cases the operator should hope for the best and prepare for the worst. It is unwise to explore with a probe: a non-penetrating wound may be turned into a penetrating one, and infection may be carried through a small tear that might otherwise have sealed off. The wisest course is to clean thoroughly the more superficial layers, to close the wound partially (leaving a drain or pack down to that part which lies nearest the joint cavity), and to immobilize the whole limb. If after a week there is no reaction in the joint, movements may safely be started.

Wounds Caused by Indelible Pencil Lead

These wounds are sufficiently common and sufficiently serious to demand attention. Indelible pencils are beloved of school children. The leads are large and brittle, and may be broken off accidentally by a child in falling on the point, or intentionally by one in need of pellets for an air gun. The wound is usually a small punctured one which emits a copious purple discharge, often for weeks at a time. The dye is toxic, and may even give rise to constitutional symptoms due to absorption. Locally it is taken up by phagocytic cells, which form a granulomatous mass that persists till the last of the dye is eventually discharged or the whole area is extruded as a slough. These small wounds should be excised as soon as their nature is recognized.

The November issue of the *Bulletin de l'Office International d'Hygiène Publique* includes articles on typhus in Egypt, India, and Rumania, Weil's disease in the United States, paralysis following anti-rabic treatment, progress made in the quarantine services in the United States, and the work on nutrition in India.

INTERNATIONAL HEALTH

SURVEY BY THE PERMANENT COMMITTEE

The report of the medical director of the International Health Office of the proceedings at the session of the Permanent Committee in October, 1937, has now been issued.¹

Aircraft and Yellow Fever

New accessions to the International Sanitary Convention for Aerial Navigation of 1933 were reported from the Republic of Liberia and several British protectorates and possessions. A general list of the notifications under the various categories of aerodromes envisaged by the Convention has been published by the Office and will be revised from time to time. A detailed survey of such aerodromes in the French colonies was submitted and an account was received of the organization and measures adopted in the United States against yellow fever. Further information was received on the degree of infestation of African countries by mosquito vectors of yellow fever and observations were communicated on the insect content of aircraft arriving at Khartum. The new form of the journey log book has been adopted by the International Commission for Air Navigation and will be put into force from June 1, 1938.

On certain specific questions submitted to the committee decisions were reached as follows:

(a) Measures to be taken under the Convention against yellow fever must be applied to all passengers using an international line, including those who do not leave the limits of one territory. The possible risk is no doubt small, but in certain regions it must be kept in mind.

(b) Article 38 may be considered as being complied with by the establishment, in areas in which the risk of infection by the yellow fever virus exists, of refuelling aerodromes to be used for short stops only, during daylight, even if such aerodromes do not possess screened buildings for the passengers and crew; no passengers must embark from them and they must not be used for any other purpose than refuelling. (The delegate from British India expressed his reserves on this point.)

(c) Hospitals in the near neighbourhood of aerodromes may be permitted to take the place of special buildings for passengers required under Article 38 (d) of the Convention.

(d) An area can only be officially considered infected or suspected if yellow fever has been diagnosed and notified in it (the delegates from British India and the Dutch East Indies expressed their reserves on this point); such a notification relating to one area must not be considered as rendering the whole country infected.

In the course of the first nine months of 1937 yellow fever has been rather more frequent in Africa than in the immediately preceding periods.

Small epidemics at Accra and Mepom (Gold Coast) occurred, and single cases were notified at Brazzaville and Bangui in French Equatorial Africa, both of which are areas in which yellow fever had not previously existed. In South America yellow fever was notified from Colombia and from Peru—the latter being the first notification for a long time—as well as from the States of Matto Grosso, Minas Geraes, and Sao Paulo in Brazil. In the Anglo-Egyptian Sudan fresh work has confirmed the high proportion of sera positive to the mouse protection test, the proportion reaching 70 to 80 per cent. in the region of the Nuba mountains. It would seem that yellow fever existed there in 1936, in the neighbourhood of Kau: a large number of sera of children under 10 years old were positive in 1937, while in 1935 all sera of children of the same age were negative. That of a European doctor who had lived in the area in 1936 was negative before

¹ Paris: Office International d'Hygiène Publique, 195, Boulevard Saint-Germain.

often possible to approximate the edges of the wound with strapping.

In the Carrel-Dakin method the wound is similarly opened, and Carrel tubes are put into each of the main compartments of the wound. These are rubber tubes, a quarter of an inch in diameter, closed distally by a silk ligature and perforated for two or three inches proximal to this by pairs of holes, one millimetre in diameter, at every half-inch. The skin opening may be partly closed again with stitches. Gauze is lightly packed round the entering tubes, and the whole part is covered with an abundant dressing of "fluffed" gauze and wool, through which the tubes are brought in a bunch. Thereafter half an ounce of Dakin's solution is injected under pressure through each tube every two hours, night and day, either with a glass syringe or from an ampoule the outlet of which is controlled by a spring clip at least four feet above the wound. The limb need not be removed from the splint, nor need the dressings be changed, until sepsis has been overcome and the tubes can be removed. Immobilization is therefore entirely adequate. (It is an essential of the Carrel-Dakin method that the injections should be made under pressure, yet even to-day it is not uncommon to see the tubes joined up to a continuous-drip apparatus. With low pressure and continuous flow most of the holes will become blocked and the fluid will trickle from a few only; with high pressure an even jet will emerge from all the holes in all the tubes.)

The hot fomentation is attacked on all sides, but it remains one of the most admirable methods for the temporary treatment of superficial sepsis. Cuts, grazes, and tears which look dirty, and stitched wounds the skin edges of which have become red and angry after forty-eight hours, will usually clear up like magic if fomented four-hourly for one or two days. The hot boracic fomentation does not rely on heat, boracic, or lint; the heat is evanescent, the boracic harmless to bacteria, and the lint one of the worst absorbents. The magic in the dressing lies in its power of capillary absorption—the power of a dish-cloth soaked and wrung nearly dry to mop up milk. The only requirements of such a dressing are that it shall be sterile or antiseptic, highly absorbent, moist but not wet, and kept moist throughout. Surgical gauze, wrung out of a one in four solution of warm eusol, fluffed out over the wound to the thickness of one inch and then covered with oiled silk and wool, forms the best compress.

Cut Tendons

The general principles of wound treatment apply equally to those involving tendons, and indeed abolition of infection and healing by first intention are of extreme importance if any useful amount of independent movement is to be obtained in the sutured tendons. Cut tendons are most commonly encountered in wounds of the wrist, palm, back of the hand, or fingers. These wounds are usually caused by broken glass or slipping bread-knives, and are therefore clean-cut and not grossly contaminated. In wounds due to broken glass it must be remembered that a great many tendons, and one or more nerves and arteries, may have been cut through an apparently small wound, and that broken fragments of glass are often lying loose in the deeper parts of the wound, and may be left behind unless a careful search is made for them. The cardinal points in the repair of such a wound are recognition of all cut tendons, exact anatomical repair, relaxation after suture, and early movement.

An exact analysis of the damage is best made by testing movements in the conscious patient, and determining

in this way which tendons have been cut. The recent Fellow may feel certain that his anatomical knowledge will allow him to identify every severed structure once the wound has been opened in the bloodless field allowed by a tourniquet. But he will be surprised to find how the synovial sheaths, structures hardly seen in the dissecting room, are converted by effused blood and the oedema of injury into gelatinous opaque masses in which cut ends are difficult to see, let alone label. The operator must be prepared to cut away enough of this red jelly, and by tabulating the proximal end according to its anatomical site, and checking the distal end according to the movement it produces, pair off all tendons which he knows to be cut. Elaborate suture of tendons is a mistake; it takes time, the extra suture material produces an extra reaction of repair, and the average result is not equal to that obtained by simple means. A single stitch of 00 catgut on a very fine cutting needle should be passed through both ends of each tendon in the same plane about three-sixteenths of an inch from the cut surface, pulled enough to appose but not angulate the ends, and tied. When all have been sutured the synovial sheath is wrapped over the group with one or two interrupted stitches of the same material and the wound closed.

After suture the limb should be splinted in such a position as to relieve tension in all the repaired tendons—for example, in cut wrist, with the wrist flexed. The position of relaxation must be maintained in any case for a week, or till the skin stitches have been removed and the clean healing of the wound is assured. The time when movement should be started varies; early movement favours freedom from adhesions, but risks the security of the suture. On the whole, it may be said that flexor tendons, lying in fibrous tunnels and enclosed in synovial sheaths, are much more liable to form adhesions than the extensors in their indefinite synovial and areolar coverings. Movement of cut flexor tendons should therefore be started after a week, whereas cut extensor tendons may be immobilized up to three weeks. The movements in either case should at first be voluntary.

The finger tendons are often severed through very small punctured wounds, or in the depths of a cut that appears to lie some distance away, and the injury may not be recognized by the patient for some days. Suture during the healing period should be avoided, being unsafe and unlikely to give a good functional result. If the case is not seen within twenty-four hours it is best to wait till the wound has healed and then to explore in a clean field, find the severed ends, and suture them. Suture of the extensor tendons in the fingers is nearly always a success; suture of the flexor tendons is nearly always a failure because of the great likelihood of adhesions in the rigid tube of the theca. Cut flexor tendons must nevertheless be repaired, and the theca must be opened to reach them by an incision along its side, as has been taught in the drainage of sheath infections. The tendon should be sutured with the finest intestinal catgut, and voluntary movements of the gentlest type encouraged from the first day. A gloomy prognosis will prepare the patient for the probable result, but allow jubilation over the rare success.

Cut Nerves

Nerve injuries due to wounds are rarely met with in civil practice except in cuts of the wrist, where the median or ulnar nerve, or both, are very often severed. As with tendon injuries, the existence of a nerve lesion should be established by the preliminary clinical investigation and not found accidentally. If the ulnar nerve is known to be

PRAECORDIAL LEADS IN ELECTROCARDIOGRAPHY

A JOINT MEMORANDUM

At the request of the Council of the Cardiac Society of Great Britain and Ireland we print below a Memorandum on Praecordial Leads in Electrocardiography. Many different positions have been used for the electrodes in obtaining these electrocardiograms, and much confusion has arisen from the different methods in use. As it has been possible for the Cardiac Society of Great Britain and Ireland and the American Heart Association to reach agreement it is hoped that these joint recommendations will be useful, both to those working at the subject and to all others who are interested.

Recommendations for Standardization

In the last few years electrocardiographic leads in which an electrode placed upon the praecordia is paired with an electrode in contact with some part of the body distant from the heart have come into widespread use. The confusion which has resulted from the lack of uniformity and precision in the technique and nomenclature employed by different observers in connexion with leads of this kind has led to an almost universal desire that a standard practice be established. To this end the Cardiac Society of Great Britain and Ireland and the American Heart Association have each appointed a committee to consider this matter and make recommendations. The two committees have conferred and have agreed jointly to make recommendations with reference to the routine use of a single praecordial lead. It is understood that either committee may make additional reports with reference to multiple praecordial leads and other matters not dealt with in the present report.

1. It is recommended that those who employ a single praecordial lead place the praecordial electrode upon the extreme outer border of the apex beat, as determined by palpation. If the apex beat cannot be located satisfactorily by palpation the electrode may be placed in the fifth intercostal space just outside the left border of cardiac dullness, or just outside the left mid-clavicular line if percussion of the heart is unsatisfactory. Where praecordial leads are taken by a technical assistant, the position for the praecordial electrode should be marked on the chest by the physician.

2. It is recommended that a single praecordial lead in which the praecordial electrode has the location specified in the preceding paragraph be known as lead IV B when this electrode is paired with an electrode in the left interscapular region; lead IV R when it is paired with an electrode on the right arm; lead IV L when it is paired with an electrode on the left arm; lead IV F when it is paired with an electrode on the left leg; and lead IV T when it is paired with a central terminal connected through equal resistances of 5,000 or more ohms to electrodes on each of the three extremities mentioned.

It is suggested that for all ordinary purposes lead IV R or lead IV F be employed. The latter lead should have the preference until it has been established that the former, which is somewhat more convenient, is equivalent to the latter for all practical purposes, or yields results of equal value.

3. It is recommended that in taking the praecordial leads specified the galvanometer connexions be made in such a way that relative positivity of the apical electrode is represented in the finished curve by an upward deflection (a deflection above the iso-potential level) and relative negativity of the apical electrode by a downward deflection. It is urged that this convention be adhered to in the case of praecordial leads other than those specified,

and also in the case of all leads in which one electrode is placed much closer to the heart than the other. In other words, it shall be the standard convention in taking such leads to make the galvanometer connexions in such a way that relative positivity of the electrode nearer the heart is represented by an upward deflection.

4. It is recommended that with the galvanometer connexions made as described in the preceding paragraph the deflections of praecordial leads be designated by the symbols P, Q, R, S, and T, and that in the application of these symbols the same conventions be employed as in the case of the standard limb leads.

5. It is recommended that in taking praecordial leads the electrocardiograph be so adjusted that a deflection of 1 cm. in the finished record corresponds to a potential difference of one millivolt, as in the case of the standard limb leads. Any reduction in sensitivity made necessary by very large deflections should be clearly indicated on the curve, preferably by photographing the effect of introducing a potential difference of 1 mv. into the galvanometer circuit.

6. It is recommended that the greatest dimension of the apical electrode employed in taking the leads specified in this report be 3 cm. or less. A circular electrode between 2 cm. and 3 cm. in diameter should ordinarily be employed.

7. It is recommended that the terms lead IV (R, F, etc.), apical lead, apex-leg lead, etc., be used henceforth only in connexion with the leads specified in this report.

The above recommendations have been drawn up by the following two committees, working in co-operation:

Committee of the Cardiac Society of Great Britain and Ireland

D. Evan Bedford (London)
John Cowan (Glasgow)
A. N. Drury (Cambridge)
I. G. W. Hill (Edinburgh)
John Parkinson (London)
P. H. Wood (London)

Committee of the American Heart Association

Arlie R. Barnes (Rochester)
Harold E. B. Pardee (New York)
Paul D. White (Boston)
Frank N. Wilson (Ann Arbor)
Charles C. Wolferth (Philadelphia)

These joint recommendations have been approved by the Council of the Cardiac Society and by the American Heart Association, who now authorize their publication. The following addendum to the joint report has been made by the Cardiac Society.

Addendum by Cardiac Society

1. The above report deals with the nomenclature and technique for obtaining a single praecordial lead suitable for routine clinical work. The committee of the Cardiac Society had insufficient evidence available to permit their making recommendations in respect of multiple praecordial leads. The American Heart Association will, however, draw up such recommendations, and, when published, copies of these will be available for those specially interested on application to the secretary of the Cardiac Society (Dr. Maurice Campbell, 25, Upper Wimpole Street, London, W.1).

2. In using either of the two standard praecordial leads—for example, lead IV R or lead IV F—the correct polarity (paragraph 3) is obtained as follows. The lead switch is turned to lead I. The L.A. terminal is connected to the praecordial electrode. The R.A. terminal is connected to the distant electrode—for example, to the right arm for lead IV R, or to the left leg for lead IV F.

and positive after his stay; in the interval between these two examinations he had had a slight attack of fever lasting four to five days.

Virus attenuated by tissue culture, without the addition of immune serum, has been used with success in England on more than 600 persons with no serious reactions. In North and South America the Rockefeller Foundation uses a virus grown on tissue from chick embryos from which the head and spinal cord have been removed. This has been used without immune serum on more than six thousand persons with a proportion of 5 to 8 per cent. of slight reactions on the sixth or seventh day after vaccination. Two to six months after vaccination fifty-one out of 2,200 persons vaccinated by various methods showed jaundice.

Typhus Fever

Although fairly frequent in Czechoslovakia between 1920 and 1923, typhus has now practically disappeared from that country, except in the mountainous region of the north of Russian Sub-Carpathia, into which it is thought to be introduced from Poland by smugglers. The local population is comparatively immune, but persons coming from other parts of Czechoslovakia are much more severely attacked. Weigl's vaccine has been used since 1934 for persons particularly exposed to infection; no case of the disease has occurred up to date in 740 persons vaccinated.

In the United States louse-borne typhus does not seem to occur, but 1,662 cases of murine typhus transmitted by fleas were notified in 1936, the majority being from the States of Georgia, Texas, and Alabama.

In Morocco three serious outbreaks occurred following the bad harvest of 1936—near Marrakesh, at Fez, and at Casablanca. Blanc's living vaccine attenuated with bile was used to inoculate the great majority of the natives in the threatened areas; 44,655, 2,962, and 146,283 persons were vaccinated in the above three areas respectively. This mass vaccination was followed by a sudden fall in the epidemic curve, even although no other prophylactic measures such as delousing were employed. According to carefully controlled mass observations the total percentage of reactions was 0.61 among the natives and 13 among Europeans.

In Tunisia endemic typhus has persisted in a few areas and broke out between November, 1936, and June, 1937, with unusual virulence. The results of the classic methods of prophylaxis having therefore been judged insufficient, it was decided to employ, in addition to isolation of infected persons and delousing, vaccination with Laigret's vaccine (living murine virus incorporated in egg yolk); this can be dried and suspended in oil at the time of inoculation, and can therefore be sent considerable distances and used by doctors on the spot. In Tunisia 3,601 vaccinations were carried out in 1935-6, 27,941 in 1936-7, and it is hoped to raise the figure to 150,000 for 1937-8. Thirty-two cases of typhus with no deaths occurred in vaccinated subjects, but twenty-seven of these, fell ill during the first fortnight after inoculation. The incidence of typhus in the months following inoculation was 0.9 per 1,000 in the vaccinated and 11 per 1,000 in the non-vaccinated of the same communities. Three cases of murine typhus, with a rash but of an ambulatory type, were produced by vaccination.

Post-vaccinal Encephalitis

As regards post-vaccinal encephalitis in various countries, five cases occurred in Great Britain in 1936 and three cases in the first eight months of 1937; five of these eight were fatal. Four of the cases were in young infants, the remainder were primary vaccinations in children of 10 to 15 years. In Germany five cases were confirmed in 1936, two in children of 3 months and 1 year, the remainder in children of 3 and 4 years old. In Italy five cases occurred in 1936 and six in 1937 out of

1,104,520 primary vaccinations and 1,205,971 revaccinations in 1936 and the spring of 1937. All the cases followed primary vaccinations, and six occurred in children of 10 to 13 months, while five were in children of 2 to 8 years. In Sweden, during the period 1924-36, fifty-four cases were notified (forty-three primary vaccinations and eleven revaccinations), of which eleven occurred in the last four years. No case was noted in the first year of life, six were in children of 1 to 2 years. The highest proportion of cases to vaccinations appears to occur in the age period 5 to 10 years. Cases are scattered throughout the country and their frequency does not appear to be influenced by epidemics of poliomyelitis.

Other Infectious Diseases

Tuberculosis.—Communications on mortality from tuberculosis in rural areas as compared with urban, with special reference to females, were received from Germany, Denmark, the United States, Great Britain, France, Italy, and Yugoslavia. Measures in force with the object of preventing tuberculous infection of school children by teachers and by one another were communicated by the delegates of nine countries.

Poliomyelitis.—Studies of several epidemics of poliomyelitis in Sweden have thrown considerable light on its epidemiology. The disease appears in several areas of a district at the same time, and may be presumed therefore to depend on some external factor. Rainfall or thaws seem to occur some ten to twenty days before each outbreak, and cases appear first in the country and then spread to the towns, possibly through unpasteurized milk. Cases of reinfection have been noted and specific immunity does not appear to be important. In Italy, on the other hand, multiple cases in families or schools are practically never observed, nor is there a relation to the rainfall. In Switzerland, as compared with an average annual incidence of 300, 1,269 cases occurred in 1936 and 1,088 in the first ten months of 1937. Family cases are very rare but occur more frequently as an epidemic progresses.

Scarlet Fever.—In the United States scarlet fever continues to be mild in character. The case incidence is 200 per 100,000 population and the death rate is about 1 per cent. Active immunization with Dick toxin makes little progress, except among those specially exposed to risk, such as nurses.

Bacillary Dysentery.—In the Netherlands Shiga-Kruse bacillary dysentery has disappeared since the beginning of the century, but small epidemics are fairly frequently observed due to Flexner's or the Y bacillus, and particularly from Sonne's bacillus. Cases are mild, but deaths may occur in children and old persons. The principal prophylactic measure is the discovery and elimination of carriers among food handlers.

Rabies.—Work at the Pasteur Institute of Tangier goes to explain why vaccine prepared by the method of Högyès has caused more frequent and severe paralytic accidents than other antirabic vaccines. It has been shown that the virulence even of a fixed virus increases very greatly by repeated passage through rabbit spinal cord. Högyès's original dilution was 1 in 10,000, but a dilution of 1 in 900,000 may be fatal.

L. M. Davidoff and C. G. Dyke (*Amer. J. Ophthalm.*, September, 1937) describe a syndrome comprising increased cerebrospinal fluid pressure, headache, marked papilloedema, and failing vision, but seldom vomiting. It is often associated with otitis media. The encephalograms are normal, the cerebrospinal fluid clear, and there are usually no abnormal neurological signs. The patients are mostly under 30 years of age, the duration of symptoms being under two years. Some of the fifteen cases they record showed slight signs of involvement of the pyramidal tract. Dehydration treatment was used in the majority of the cases with good results.

Keratoconus has been shown in many instances to be a manifestation of disorders of endocrine glands (thyroid and gonads). Von Imre is of opinion that there is a close connexion between acute and chronic glaucoma and abnormal folliculin production. The folliculin production of four glaucomatous patients, examined by reliable biological methods, proved to be exceedingly low. The production of prolactin was in every case normal. He points out that there is an undoubted connexion between the changes of the intraocular tension and the pituitary during pregnancy.

Patients suffering from retinitis pigmentosa are treated nowadays with menformon, and in many cases improvement follows and the progression of the disease is arrested.

Prevention of Blindness

At the meeting of the International Association for Prevention of Blindness Dr. Bailliart (president) read an introductory address. Mr. A. F. MacCallan (London) discussed the measures adopted in Egypt for the prevention of blindness. The ophthalmic campaign inaugurated in Egypt thirty-four years ago, and especially the establishment of travelling ophthalmic hospitals, has reduced the incidence of blindness among patients attending ophthalmic hospitals by one-third. Dr. F. Park Lewis (New York) discussed the responsibility of the ophthalmologist in the conservation of sight and the prevention of blindness. The prevention of blindness is as worthy of consideration by ophthalmologists as either research or surgical care in affections of the eyes. The blindness that comes from negligence, from ignorance, from indifference, and the crudities of living and its mismanagement is universal.

Dr. Joseph Minton (London) read a paper on prevention of industrial eye injuries. An investigation was carried out by him at the Royal Eye Hospital, London, where over 7,000 patients suffering from industrial eye injuries are attended to every year. The present high numbers are due to (1) non-provision of safety measures by employers, and (2) the attitude of indifference shown by workmen to the risks entailed in their work and their negligence in using preventive measures supplied to them. Following his investigation he has organized at the outpatient rooms of the Royal Eye Hospital a museum of preventive measures. The patients have thus an opportunity of studying the preventive appliances at the time of attendance at hospital, and thus choosing the most suitable one for their type of work. If other hospitals situated in industrial areas would take an interest in preventive work a diminution of eye injuries and, with it, of resultant total or partial blindness would follow.

Mr. Lewis H. Carris (U.S.A.) read a paper on the role of the social worker in a campaign for the prevention of blindness. Educationists, public health officials, nurses, industrialists, sanitary engineers, social workers, and all in any way concerned in human welfare must take their rightful place in the attack upon this social enemy. To the world at large we must teach the causes of blindness and defective vision, the place of nutrition and hygiene in relation to eye health, methods of safeguarding the eye against injury and harm and of keeping it in a state of greatest possible usefulness.

The Congress was attended by 600 delegates from all countries. On December 9 they were entertained at the Royal Palace by King Farouk. Visits were arranged to the hospitals in Cairo, and excursions to museums and places of interest. The next international congress will be held in Vienna in 1941.

The Diabetes Society of New York has issued a card for diabetics to take about with them containing the patient's name and telephone number, and stating that he has been treated with insulin, and that on loss of consciousness he should at once be injected with glucose solution.

CROYDON TYPHOID INQUIRY

FINAL SPEECHES

The Croydon Typhoid Inquiry, which had been expected to end on January 11, the tribunal sitting late for the purpose, had to hold a further meeting on the following day to enable Sir Walter Monckton, K.C., to conclude his speech on behalf of Croydon Corporation. His final address to the tribunal consisted largely of a defence of the water department and the borough engineer, but he also dealt with certain complaints as to "slowness" which had been made against the medical officer of health.

Sir Walter Monckton reminded the tribunal that on November 1 the medical practitioners in the neighbourhood where the first few cases had occurred were notified to look out for typhoid. In the course of his cross-examination Sir William Wilcox had agreed with him that, so far as it went—though he thought it had not sufficient life in it—that was an adequate notification to put them on their guard about the existence of typhoid in the district. It was necessary to secure two things: first to put the doctors on their guard, and secondly, to prevent premature publication of something which ought not to have been published because it would create a scare or panic. If medical practitioners knew that there was a case or two of typhoid in the district where they practised they would suspect each case of illness of being a typhoid case until they were satisfied that it was not, and therefore the notification by the medical officer of health was all that was required. It was true that one could not draw a line and say that within a particular area every doctor should be notified; nevertheless, all the doctors practising in the particular district were notified on November 1, and on November 4 all the doctors in Croydon were notified. It was quite plain that any method of the kind was subject to criticism, because it must leave out of account some doctors who would be coming into the area, but when the 150 or more doctors who actually practised in Croydon received the notification it was to be presumed that their colleagues who came in from outside would hear of it. The advantage of notifying the doctors was not only that they were the people who saw the illness at its beginning, but they were the only people who could be trusted to pass on the information in a way which would not cause uninstructed alarm. A doctor could pass on explanations to his patients and their families, while public notification might lead to misunderstanding and panic.

With regard to the cause of the outbreak, Sir Walter Monckton submitted that it was still impossible to put the finger with any confidence upon a particular cause. The possibility of an unidentified carrier and of pollution being received in some way from the gathering ground could not be excluded. Sir William Wilcox had taken the view that the gathering ground was the most probable source, but Sir William had not in mind the fact, which was assumed by all the rest of those concerned in the Inquiry, that for a period there was a carrier actually at work in the well, and he might to some extent have modified his view if he had had that fact present in his mind. Among the many people who were on the gathering ground it had not been possible to investigate far enough to rule out a potential source of infection there. Looking at the gathering ground as a possible source, one's mind turned first to the latrine trench that was dug thirty-five yards from an adit. It had not been possible to identify all the workmen—100 or more—who were engaged there from May to November, and to eliminate the possibility of carriers. Steps had been taken to examine some, and so far as the investigations went they were negative.

In conclusion he suggested how easy it was to be wise after the event. It was scarcely possible to help applying to things as they had turned out to be a standard which

CAIRO OPHTHALMOLOGICAL CONGRESS

[FROM A CORRESPONDENT]

The fifteenth International Ophthalmological Congress was held in Cairo from December 8 to 14, 1937. The two main subjects discussed were hypertension and retinal arteriosclerosis, and endocrinology and its relation to the eye.

Retinal Arterial Hypertension

Dr. H. P. Wagener and Dr. Norman M. Keith (the Mayo Clinic), Dr. Bailliant (Paris), and Dr. Y. Koyanagi (Japan) read the opening papers on the subject of retinal arterial hypertension.

The ophthalmologist, because of the wider and more intimate knowledge of the clinical details of retinal pathology, should be better equipped than the physician to observe the reactions in the retina which are associated with an elevation of blood pressure and systemic vascular disease. If it can be assumed, as seems logical, that the visible reactions in the retinal vessels are similar, though at times disproportionate, to the invisible reactions taking place in vessels of similar size throughout the body, then an explanation of the mechanism of these reactions in the retina will go far toward solving the mechanism of diffuse vascular disease. The responsibility of the ophthalmologist in the solution of this problem is great and his opportunities are wide, for he is able to see these vascular changes from their inception and to study their modes of origin and progression.

Evidence accumulated in the fields of physiology, pathology, and clinical investigation indicates that arterial hypertension is an expression of a diffuse disease or abnormal condition of the arterioles throughout the body. The lesion of the arterioles results in an increase in the peripheral resistance in certain regions or in the whole of the arteriolar bed. The narrowing of the lumen of the arterioles, which is the apparent cause of the increased resistance, is not structural in the earliest phases of the disease. It must be regarded as due to increased tonicity of the vessel wall, to spastic constriction, or to a combination of the two. Whether the tonic or spastic constriction is due to the action of a pressor substance directly on the arteriolar wall or through the medium of the sympathetic nerves, or simply to increased vasomotor stimuli, is not known. If the causative factor of the arteriolar narrowing continues to operate, histologic changes develop ultimately in various parts of the arteriolar system—for example, in the peripheral muscles, the heart, the kidney, the brain, and the retina.

Classification of Essential Hypertension

Both these factors—functional narrowing of and structural wall changes in arterioles—appear to be present in the usual case of diffuse arteriolar disease of the so-called "essential hypertension" type. On the basis largely of the dominance of one or the other of these factors in a particular case, it is possible to classify cases of "essential" hypertension into various groups, in each of which the probable course of the disease and the life expectancy of the individual patient can be foretold with a reasonable degree of accuracy.

Dumas divided essential hypertension into three phases. In the first or silent phase the patient is essentially symptomless. In the second or established phase the disease has become organic and visceral lesions are present. Cerebral haemorrhages, cardiac failure, or uraemia may terminate this phase. It is possible, however, for the hypertension to pass into the third or involutional phase, in which the blood pressure drops and arteriosclerosis dominates the picture—the hypotensive stage of hypertension. According to Bonamour the retinal changes in Dumas's first phase are spastic in type. The blood pressure in the central artery of the retina is likely to be

elevated disproportionately to the blood pressure in the brachial arteries. Patients may complain of transient loss of vision. Post-spastic thrombosis of the central artery may result in permanent loss of vision. In the second or established phase retinitis develops in cases which are running a rapidly progressive course. If the disease progresses more slowly sclerosis develops in the retinal arteries as a defence reaction. In the third or involutional phase the sclerosis in the retinal arteries is likely to be quite marked, and lesions such as arteriosclerotic retinitis and retinitis circinata are characteristic. In Bonamour's opinion retinitis of the hypertensive type is essentially vasospastic in origin. As a result of arteriolar constriction reactional dilatation and stasis develop in the capillary bed and serous and haemorrhagic transudations take place into the retina.

Albuminuric Retinitis

The problem of the pathogenesis of "albuminuric retinitis" has been a consuming one almost since the beginnings of our knowledge of albuminuria as an expression of disease of the kidneys. Bright himself recognized that loss of vision was a symptom in cases of certain patients with albuminuria. Most physicians at present agree that a retinitis of "albuminuric type" can occur in cases in which no evidence of renal insufficiency can be demonstrated clinically, and in which, at necropsy, the kidneys show no evidence of primary nephritis. The most logical explanation of the mode of origin of "albuminuric retinitis" seems to be that of Volhard, who regarded both the arteriolar sclerosis of Verwey and the retinitis as a result of ischaemia due to spasm of the larger arterioles. Volhard's conception of ischaemic or angiospastic retinitis seems to be more generally applicable than any other to the retinal complications of hypertension and nephritis, and to permit of more ready comparison of these complications with the other features of the systemic disease.

Wagener and Keith reported in 1928 on a condition which they termed "the malignant hypertension syndrome." The objective findings are persistently elevated blood pressure, diffuseness of arterial and arteriolar thickening through the body, minimal changes in the renal parenchyma, and retinal changes. The important retinal alterations are the marked spastic and organic narrowing of the arterioles, with diffuse retinitis and oedema of the disks. The characteristic symptoms are nervousness, asthenia, visual disturbances, and dyspnoea on exertion. All observers are agreed that the patients of this group are in a very serious condition. A follow-up of 146 cases showed that 80 per cent. of them died within one year.

Dr. Bailliant, dealing with the clinical part of retinal arterial hypertension, stressed the value of his dynamometer, which estimates the diastolic blood pressure in the retinal arterioles, which is about 40 per cent. of the diastolic pressure in the brachial arteries. The pressures as measured by this method furnish a ready and probably fairly reliable method of determining variations from the normal in pathologic states.

Endocrinology in Relation to the Eye

The discussion on endocrinology and its relation to the eye was opened by Dr. Snapper (Holland), Dr. von Szily (Germany), Dr. von J. Imre (Hungary), Drs. Jeandelize and Drouet (France), and Dr. Le Cascio (Italy).

Recent investigations have shown that various disorders of the sexual glands are associated with pathological changes occurring in the eyes. Periodic haemorrhages of the subconjunctival tissue, recurring conjunctival inflammations, or especially phlyctenular kerato-conjunctivitis are not rarely found in close relation to menstruation. Filamentary keratitis following atrophy of the lachrymal glands and often combined with arthritic processes as a rule develops in women with ovarian disorders or in the beginning of climacteric.

Reports of Societies

NUTRITIONAL THERAPY DURING PREGNANCY

At a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on January 11 a discussion took place on nutritional therapy during pregnancy. Dr. J. W. TREYAN was in the chair.

Analysis of Diets taken by Pregnant Women

Dr. R. A. McCANCE of the Biochemical Department, King's College Hospital, said that the results he had to communicate were reported very briefly to the British Medical Association Meeting at Belfast in July last, but the work had been considerably extended since then. The subjects of the investigation were 116 pregnant women with varying incomes, who weighed all the food they ate for one week. He believed this was the first investigation of the kind made in this or any other country, but those concerned took no credit for that, because it was an investigation which should have been made years ago in any country interested in the well-being of its citizens. The better-class women were not all visited personally, but the poorer women were visited every day, any records which were suspect were thrown out, and it was believed that these 116 women carried out their part in the investigation correctly enough to provide records of real value. The composition of the diets was calculated from food analyses made at King's College Hospital. The heights and weights of the women were measured, and the amount of haemoglobin in the blood was estimated (by Haldane's method) in seventy-seven of them. About fifty of the women were the wives of unemployed miners in South Wales and Durham, and the others belonged to three groups of rather more than twenty, each consisting respectively of the wives of employed labourers in Bermondsey, the wives of better-off artisans in Camberwell, and women of the professional classes. The results were shown in the following table:

Income (Less Rent) per Head per Week	No. in Group	Haemo- globin %	Calor- ies per Day.	Total Prote- ins gms. p.d.	Animal Proteins gms. p.d.	Cal- cium gms. p.d.	Phos- phorus gms. p.d.	Iron mgms. p.d.
Less than 6s.	16	76	2,211	60	28	0.51	0.80	8
6s. to 9s.	23	79	2,158	64	36	0.53	0.92	10
9s. to 15s.	19	80	2,194	66	37	0.52	0.99	12
15s. to 25s.	14	81	2,471	75	36	0.75	1.22	13
25s. to 40s.	13	90	2,781	86	55	0.75	1.32	14
Over 40s.	22	—	2,517	80	55	0.92	1.44	14

With rising income the intake of milk went up, and would have gone up much more steeply but for the fact that the women in the two poorest groups were being supplied with considerable amounts of milk from the public authorities; this went a long way to explain the increase in calcium. White bread fell as incomes went up, but brown bread stayed level in the first three groups and then went up. Total flour showed a certain falling off with income. The intake of jams and marmalades went up. Eggs rose with income, as did raw fruit, meat, and fish, and green vegetables rose strikingly. It could be said that the investigation had afforded evidence of profound nutritional deficiency in the poorer classes.

The next question as to whether the well-to-do women were perfectly nourished was difficult to answer because of the absence of criteria. On comparing the diets of these professional women with the recommendations of the League of Nations Committee on Nutrition, it appeared that they consumed an average of 2,517 calories a day, whereas the Committee's recommendations were from 3,000 to 3,500, but, in his view, these recommenda-

tions were too high. The calcium intake each day, 0.92 gramme, was very much below the League of Nations' recommendation (1.60 grammes), and so was the phosphorus, 1.43 grammes a day, the League's recommendation being 1.90 to 2.60 grammes. It was possible that even women of the professional class were not being nourished during pregnancy in the best possible manner, but well-to-do women with plenty of money to spend on food would find it difficult to consume up to the protective food level suggested by the League of Nations.

As for remedies there appeared to be four possible methods: (1) food education; (2) increased income, or, alternatively, the cheapening of essential foods; (3) communal feeding in some form; and (4) medicinal treatment with mineral or vitamin supplements. Probably a mixture of the four methods would give the best solution.

Concentrated Food Substances in the Diet

Dr. MARGARET BALFOUR gave a brief account of the work of the National Birthday Trust Fund, organized to help women in the distressed areas. This work began in the Rhondda Valley, where the maternal mortality for the seven years previous to 1935 averaged 7.22 per 1,000 births. The scattered nature of the population made it difficult to organize meals, and as the local authority was already giving milk the Birthday Trust determined to supply dry foods from ante-natal centres. At the end of 1935, the first year of the experiment, there was a reduction in mortality; in 1936 the scheme was extended to other areas in South Wales and to three areas in the north of England, and again the mortality fell. The food given consisted of a certain milk preparation and marmite, and this was continued for twelve weeks, which might be the last twelve weeks of pregnancy or, if the medical officer preferred, the nine weeks before delivery and the three weeks after. Over 10,000 expectant mothers had received the food, and among these the puerperal death rate from sepsis was only 0.09 per 1,000—that is, only one death. In a control series of 18,000 women in the same area who did not receive the food the puerperal death rate from sepsis was 2.91. The maternal deaths from other causes gave rates of 1.54 and 3.24 in the respective groups, and the infant death rate was little more than half in the Birthday Trust group what it was in the control series. The Birthday Trust women were mostly the wives of unemployed men; the mothers in the control group were more often better-class women who received ante-natal care from their own practitioner. It had been suggested that the difference was due to the fact that all the Birthday Trust women received ante-natal care, whereas only a proportion of the others did so. On the other hand, it must be remembered that the women who went to the ante-natal centres were likely to include a larger proportion with some abnormal condition in pregnancy and also a larger number of primiparae.

There was some doubt as to how far the milk foods given were taken by the women themselves, and how far they shared them with their families. The marmite contained very little protein, no carbohydrate or fat, but it was rich in the vitamin B complex, which was a neuro-muscular stimulant, and possibly when this preparation was taken in the last months of pregnancy it enabled the woman to deliver herself in certain cases when otherwise she would have had to undergo operative intervention. The vitamin B complex also had a special action on the skin and mucous membrane, and it might be that the action on the mucous membrane of the uterine passages diminished the tendency to puerperal sepsis. A new extract of yeast rich in vitamin B had been prepared, and this was being given instead of marmite in some areas in order to find out whether the beneficial effect of marmite was due to its vitamin B or to some other constituent.

General Discussion

Dr. J. W. TREYAN commented upon the high total calories recommended by the League of Nations. He was sure that he could not himself consume 3,500 calories a

it might not have occurred to one to apply had one been faced with the conditions at the time. In expressing gratitude for the patience and courtesy with which the tribunal had listened to the arguments, he said with what kindness the assessors (Sir Humphry Rolleston and Mr. Gourley) "have watched us sail our frail barque into what to them are territorial waters, but to us uncharted seas, and have observed our misfortunes with ready sympathy and kindly smiles."

Mr. H. L. Murphy, the chairman of the tribunal, said that he would endeavour to get out his report without undue delay. He added:

"We have been debating a subject upon which feelings have been very strong on both sides, and we have been here for seventeen days debating it in an atmosphere, I think I may say, of complete tranquillity, for hardly has there ever been the necessity for even a request for silence. I think that is a tremendous tribute to the orderliness and sense of fair play of the people of Croydon, and I wish to thank them very much for it."

In the course of the Inquiry about 8,000 questions were asked of witnesses, and the shorthand record extends to over 1,000 printed pages.

PSYCHIATRIC RESEARCH BUREAU

Thanks to the generous assistance of the Rockefeller Foundation a bureau for the assistance of research workers in psychiatry has been established under the auspices of the Royal Medico-Psychological Association. The committee of the Research Bureau consists of Sir Hubert Bond, Dr. J. Brander, Dr. W. T. Fleming, Professor F. L. Golla, Dr. P. K. McCowan, Dr. W. D. Nicol, Dr. G. W. Smith, and Dr. R. M. Stewart.

Aims and Methods

The objects of the Bureau are the following:

1. Any psychiatrist who wishes for special information as to what is at present known on any subject of interest to himself is invited to notify the Secretary of the Bureau. A bibliography of all recent papers relating to the subject will be sent to him, together with abstracts of such communications as may seem of great importance, and should he then desire abstracts of any particular papers, especially those published in foreign languages, they will be made for him on demand.

2. Any worker who wishes to start some particular research may on application obtain information as to what has already been done on the subject, and what methods of procedure are advised for further work.

3. Any worker who desires further elucidation on points of technique will be either advised directly from the Bureau or put into direct communication with the appropriate members of a panel of experts who have kindly consented to advise on technical questions.

4. Workers desiring the loan of technical manuals for purposes of their work may obtain them on application.

5. Workers desiring to see personally the application of methods of research or treatment or to confer personally with expert advisers will be eligible to receive small grants to enable them to do so. These grants, which will be made by the committee, are intended to cover the expense of visits of a few days to laboratories at home or abroad, and are primarily for the use of medical officers who might be unable to make such visits at their own expense.

6. A short account of recent advances in subjects of particular interest together with a fairly complete bibliography will be issued at intervals and sent to any psychiatrist who may signify a desire to receive it.

7. Psychiatrists who would like to be put into communication with other workers abroad can receive help from the Bureau.

8. Although it is very much hoped that all British psychiatrists will be members of the R.M.P.A., the services of the Bureau and the eligibility for grants is open to any psychiatrist working in the British Empire.

All communications should be addressed to Research Bureau, the Royal Medico-Psychological Association, 11, Chandos Street, Cavendish Square, London, W.1.

ROYAL MEDICAL BENEVOLENT FUND

At a recent meeting of the committee eight annuities were awarded. Forty-five grants were voted to beneficiaries, amounting to £1,204. Among thirteen new applicants the following particulars are given of two cases:

M.R.C.S., aged 70, married; wife aged 58. Invalided out of the Royal Air Force with glaucoma in 1926, he has not been in practice since, but has been able to earn a very small and precarious living by writing. This source of income is ended owing to blindness and through exhaustion of the subject. His wife has had several attacks of cholecystitis due to gall-stones, and may have to be operated on in the near future. Private income *nil*. The Fund voted £100.

Daughter, aged 60, of F.R.C.S. For twenty-nine years she has worked as a matron at two private schools, but had to give up her work in 1933 owing to phlebitis and varicose veins. She has been living on her savings, which are now reduced to £30. She has no relations who can help her. The Fund voted £36, and is obtaining assistance from other charities for this most deserving case.

Subscriptions and donations are urgently needed. Cheques may be made payable to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, London, W.1.

E. Mowinckel, H. Hansen-Reistrup, and P. J. Reiter (*Hospitalstidende*, September 7, 1937) have sought clinical evidence of vitamin deficiencies in the patients treated in a large Danish mental hospital whose diet they have scrutinized with special reference to its vitamin content. The test for vitamin A deficiency was that devised by Edmund for the detection of hemeralopia, and consisted in the measurement of the patient's reaction to light in a darkened room. The degree of intelligent co-operation required for the satisfactory performance of this test entailed the elimination of many of the patients, but 260 were found suitable. Among them were twenty-one with definite and sixty-eight with doubtful visual signs of vitamin A deficiency. A search for vitamin B₁ deficiency in the form of polyneuritis, other than alcoholic polyneuritis, revealed only one case, and that was merely a suspect case. Evidence of vitamin B₂ deficiency leading to pellagra was found in several patients, particularly among the subjects of schizophrenia and those suffering from severe chronic disturbances of the digestive system. The changes observed were partly cutaneous, partly neuritic (central neuritis). The ascorbic acid test for vitamin C deficiency not being available when these studies were started some three years ago, the authors relied on the Bexelius capillary resistance test for the demonstration of vitamin C deficiency, for which 548 patients were examined. In 6.5 per cent. of them vitamin C deficiency was thus demonstrated. Among the patients found to be suffering from it were eleven with well-defined stomatitis. The incidence of various forms of vitamin deficiency was highest among the schizophrenics, who represented 60 per cent. of the hospital's inmates. The authors conclude that though they have failed to demonstrate any marked vitamin deficiency either in the patients or their diet, the amount of vitamins A, B, and C in the diet is dangerously low. This is the more deplorable as a shortage of vitamins may in some cases profoundly influence the mental condition of the insane.

phases. The major fit, usually starting ten to thirty seconds after the injection, with a phase of generalized tonic clonus merging into the clonic phase and succeeded by a state of flaccidity, was followed by a short period of coma, and complete consciousness was generally regained in from five to ten minutes. Recovery was sometimes associated with confusion, restlessness, and mild excitement lasting a few minutes, but most patients were quiet and soon dropped off into normal sleep.

If due precautions were taken danger was insignificant. Meduna had treated 400 cases without fatality, and Dr. Cook believed that only three deaths were recorded in upwards of 1,500 cases treated by various workers. At Bexley he and his colleagues had induced over 1,400 major fits without encountering any really alarming features. Respiration might momentarily cease in the flaccid stage, but pressure on the lower ribs immediately restarted it. Transient cyanosis was usual, and might possibly be of therapeutic value. Occasional irregularity of the pulse occurred, but was quite temporary. A thorough physical examination should precede treatment, and all patients suffering from general bodily illness, especially of the heart and lungs, or any form of pyrexia, should be excluded.

Although dangerous or serious sequelae were conspicuously absent, two annoying complications tended to occur. One was local fibrosis of the injected veins, and the other was the distress and fear occasioned. Most patients feared the injections and a few reached a pitiable stage of apprehension. The distress could be lessened by giving an immediate sedative (not an anti-convulsant, such as luminal). It was his habit to give a second and larger dose immediately after an unsuccessful injection, thus reducing to a minimum the period of distress. The question of premedication had been considered, and lately he had been using hyoscine and morphine in combination, with the result that severe apprehension and distress had become a thing of the past. The only method of completely eliminating distress was that of combining insulin and cardiazol therapy and administering cardiazol during insulin coma.

Estimation of Results

After showing a table giving the collected results of a number of workers, Dr. Cook gave a summary of forty-five cases treated at Bexley. There had been remissions in twenty-four cases and no remissions in twenty-one. Of the twenty-four cases which showed remissions, sixteen showed very good remissions or recovery. In these same twenty-four cases the duration of illness had been over two years in eleven, between one and two years in six, and under one year in seven. Of the twenty-one non-remission cases, fifteen had had a duration of illness of over two years. By "recovery" he meant discharge or awaiting discharge, the patients having lost every schizoid feature. The greatest triumphs had been gained with some of the almost intractable schizophrenics whose illness had lasted more than two years. More trustworthy than statistics were the impressions of experienced clinicians and nurses. The medical staff at Bexley felt no doubt as to the value of the therapy, and the nurses, who were not likely to be carried away by a new treatment, and at first were biased against it because of the distress occasioned, were now enthusiastically in its favour.

Of the early cases of acute onset, the stuporous and confused types were generally agreed to have the best prognosis. Paranoid types were said to offer considerable resistance to cardiazol therapy, but if the case was of recent and rapid onset it was by no means intractable. Less success attended the treatment of early cases of schizophrenic excitement, especially when the predominant affective state was one of elation. This might be partly due to the tendency for cardiazol to produce a mood of euphoria and spurious confidence. When a schizophrenic illness had lasted more than three years complete recovery

was extremely rare, yet here again stuporous and vegetative subjects of catatonic type fared best, and Dr. Cook thought it might fairly be claimed that cardiazol fits could always interrupt a state of stupor.

A tendency to relapse was not infrequent in cases of incomplete remission and could easily be counteracted by a few further convulsions. If treatment was interrupted before completion relapse was common. Post-convulsional lucidity with a tendency to relapse within forty-eight hours had been observed in two cases of agitated, resistive stupor. Good results had been obtained in recurrent cases, although they might not have achieved more than a "social" remission—that is, becoming as well as they were before their illness, or at their individual best—over a period of several years.

Finally Dr. Cook touched upon cardiazol in relation to other forms of treatment, in particular insulin. Insulin and cardiazol should be regarded not as rival but as complementary methods of treatment. Their statistical results were similar, but insulin appeared to have a curative predilection for paranoid and excited syndromes, while cardiazol produced its best results in states of confusion, stupor, and distress. In ideal circumstances both methods should be available. The combined method abolished the distress associated with cardiazol, whilst retaining the beneficial effects of regular convulsions. Cardiazol had the advantage of a simple technique, requiring no large or specially trained staff, and of comparative freedom from danger, though the dangers of insulin therapy, on the other hand, were rapidly decreasing as experience of its action accumulated.

THE ASTHMA PROBLEM

At a meeting of the Section of Medicine of the Royal Society of Medicine on January 13, with Dr. H. L. Tidy presiding, a discussion took place on certain aspects of the asthma problem.

Dr. FRANCIS M. RACKEMANN (Boston, U.S.A.) said that asthma was most often a symptom of allergy, but there were a number of patients who had asthma which was not allergic in origin. Asthma and hay fever, and possibly eczema, depended upon immediate reactions of the urticarial type. These reactions, which were demonstrated by a skin test, occurred not only in persons said to be allergic but in others said to be normal, and they could be reproduced in animals. In addition to the immediate reaction a delayed inflammatory reaction could also be demonstrated twenty-four or forty-eight hours after the test had been applied. It was possible to correlate the delayed and the immediate reactions and to show that each was a part of the development of immunity. The degree of sensitiveness of asthma subjects was often extreme, and might be multiple. Thus, a baker with wheat asthma reacted not only to wheat but to rye and orris powder. Another factor was inheritance; some 60 per cent. of the individuals who were themselves sensitive stated that their father or grandfather had had similar symptoms.

The symptoms that accompanied asthma were very characteristic. The patients had a low blood pressure, a rapid pulse, and fatigued easily. Sensitivity to a skin test did not necessarily imply sensitivity to the point of producing symptoms. He had tested thirty employees in a bakery, making skin tests with wheat and other substances; seventeen of the men had partial skin sensitiveness to wheat, but only one out of the thirty had any trouble from the inhalation of wheat flour. In hay fever or specific allergic rhinitis the tissues in the nose were sensitive, and a local reaction in the mucous membrane took place on contact with grass pollen. About one-third of such persons had asthma, but the process did not advance by direct extension along the mucous mem-

day. With regard to Dr. Balfour's figures, he wished it had been possible to have controls from the same group, although he admitted the difficulty of having to deprive some women of the protective foods which were given to others. Dr. HELEN MACKAY said that in work like this it would be better to study small groups intensively. The mortality rate would be too small to be helpful, but the morbidity rate might afford a great deal of information. There was no doubt that in children small additions to the diet effected remarkable improvements in the morbidity rate, and if in children why not in adults? Professor JAMES YOUNG said that some of the Birthday Trust figures seemed almost too good to be true. To have only one death from sepsis in 10,000 deliveries almost suggested—though he could not accept the suggestion—that all the obstetric procedures against sepsis might be abandoned, and that it was sufficient to administer a little yeast to secure an adequate resistance. The control group, he imagined, consisted of women who were economically better off. This must mean that the important thing was not the quantity of food, because these better-to-do women presumably had sufficient food, but the difference must depend upon some inherent quality in the diet.

Dr. JANET VAUGHAN said that Dr. McCance's figures had demonstrated again that there was a very high incidence of some degree of anaemia in working-class women during pregnancy. She thought the justification for giving all women during pregnancy medicinal doses of iron should be considered, not only for the sake of the women themselves but for their children. Another point was that marmite had a very important haemopoietic action which was not understood and was probably not associated with any of the vitamin B constituents at present recognized. It might be associated with the vitamin B complex, but was certainly not vitamin B₁ or B₂. She quarrelled with Dr. Balfour when she said that it was better to give these medicinal remedies than to give a good round meal. In the latter case the women were being provided with a good many other necessities not included in the artificial diets. It did seem rather tragic that this magnificent experiment was being jeopardized by the omnibus type of therapy employed. It would be far wiser to study a few cases, giving them not omnibus treatment but carefully selected remedies.

Mr. A. L. BACHARACH differed from Dr. Vaughan. It was a paradoxical position that Dr. Vaughan, who was a physician, should be . . . she alleged was an experimental and . . . while he, as a laboratory worker, was "shocked by her suggestion." He believed that such an experiment would not work. It would be all very well if the women dealt with were experimental animals in the laboratory whose basic diet could be rigorously controlled so as to be adequate in all factors save one, and experiments carried out on that one variable factor. But that was not the position, and there would be a large number of women who were suffering from multiple deficiencies of varying degrees of intensity. The only result of giving to a group of individuals, who were suffering from subnutrition in other respects a single factor would be to prevent that single factor from demonstrating its full possible effect. He further said that it had been shown that diets apparently perfect in themselves were capable of very marked improvement by the addition of one or more constituents that had been previously supposed to be present in adequate amounts; no two of these additions when worked out arithmetically on paper had the same effect as when given together in practice. This was a question of integration of effects which could not be demonstrated in theory, but only by carrying out experiments. The work that was being done was of the nature of making the best of a bad job. A number of pregnant women were on a dietary level which was injurious to their health. Additions to the diet would go a long way to modify that position. It was not known exactly what dietary constituents would do this, but they were in a position to say

that certain foods and yeast products would do a great deal to bring down mortality and morbidity.

Professor J. R. MARRACK joined in the protest against the medicinal method of making up inadequacies in diet. The people concerned suffered from multiple deficiencies, and if an attempt were made to make up such deficiencies with multiple supplies of elaborate preparations peculiar difficulties would arise. It was much better to make up the deficiencies with ordinary food. Dr. PAYNE asked whether there were any sources other than milk for obtaining calcium. Dr. McCANCE replied that a large amount of calcium was necessary to the body, and milk was the only food in common use in this country which gave it. It was the most important source of calcium in British diet. Dr. MARGARET BALFOUR said that it might be very much better to give natural rather than artificial food, but this was not easy, partly owing to the economic situation and partly owing to the psychological fact that these poor expectant mothers did not like leaving their homes to go to a centre for a good meal while their husbands and children remained with scanty food at home.

CARDIAZOL CONVULSION THERAPY IN SCHIZOPHRENIA

At a meeting of the Section of Psychiatry, Royal Society of Medicine, under the presidency of Dr. EDWIN GOODALL, on January 11, a paper on cardiazol convulsion therapy in schizophrenia was read by Dr. L. C. COOK, deputy medical superintendent, Bexley Mental Hospital.

Dr. Cook began with a reference to his visit last summer to Budapest, where the treatment of schizophrenia by induced convulsions was originated by Meduna in 1934. For many years it had been known that any severe shock, whether in the nature of acute physical illness or intense psychological stimulation, occasionally produced dramatic improvement in schizophrenia. The metabolic changes in schizophrenia were unknown, but evidently they were not irreversible, and these shock methods were able sometimes to reverse them. Convulsion therapy was first introduced in the form of intramuscular injections of a camphorated oil solution, but Meduna soon discovered the advantages of intravenous cardiazol (pentamethylene tetrazol), a synthetic water-soluble compound, primarily a cardiac and respiratory stimulant. For convulsion therapy it was convenient to use a 10 per cent. aqueous solution, made up freshly every two or three days, sterilized by autoclaving at 110° C. for twenty minutes, and kept in air-tight rubber-capped bottles. Doses as small as 0.2 gramme might be sufficient to produce a fit, but 0.5 gramme (5 c.cm. of the 10 per cent. solution) was the usual initial dose. The same dose was administered as long as it produced a major fit. When the initial dose failed to produce a convulsion an increase of 0.1 gramme was given at the next injection. In practice a few increases were often necessary during a course. When once the effective dose was reached 85 per cent. of injections should be successful. Dr. Cook never found it necessary to give more than 1.2 grammes as a single dose, but he had immediately followed a subliminal dose of 1.1 grammes with a second injection of 1.2 grammes without any ill effects except slight vomiting. Fits were usually induced every three days; in some cases it might be preferable to give the injections every other day. The length of the course depended upon the subject. When improvement occurred it might be dramatic in its rapidity. When a full remission was considered to have been established it was usual to give at least three further fits to diminish the chance of relapse. In completely unresponsive cases twenty fits should be induced before the treatment was given up.

The Fit and its After-effects

The fit resembled a severe, spontaneous, generalized epileptic convulsion and showed all the characteristic

PREVENTION AND CONTROL OF ADDICTION

At the meeting of the Society for the Study of Inebriety on January 11 two papers were read under the title of "Some Official Contacts with Addiction," one by Dr. W. NORWOOD EAST, H.M. Commissioner of Prisons, and the other, dealing with the subject from the international point of view, by Major W. H. COLES, H.M. Chief Inspector under the Dangerous Drugs Acts and United Kingdom representative on the League of Nations Opium Advisory Committee.

Dr. Norwood East began with a review of the various legislation and regulations before, during, and since the war which had contributed to the prevention of alcohol and drug addiction. He mentioned particularly the following:

The Children's Act, 1908, which prevented children from being taken into licensed premises, and imposed penalties for giving intoxicating liquor to a young child except in special circumstances.

The Small Holdings and Allotments Act, 1908, prohibiting any dwelling-house or building on the holding being used for the sale of intoxicating liquors.

The Defence of the Realm Regulations during and following the war, with their various restrictions.

The decision of the Central Control Board (Liquor Traffic) in 1916, leading to the State management of licensed premises at Carlisle.

More recent legislation included:

The Road Traffic Act, 1930, with its penalties for motor drivers found to be under the influence of drink.

The Licensing (Permitted Hours) Act, 1934, enabling justices to vary the hours of opening.

The Dangerous Drugs Act, 1932, amending earlier Acts.

The Extradition Act, 1932, making it possible to include offences in relation to dangerous drugs in the list of extraditable crimes.

The Pharmacy and Poisons Act, 1933, with its attendant rules.

Various statutory Orders controlling the manufacture, possession, and distribution of narcotic drugs.

The average number of persons dealt with summarily for offences which may be placed under the general heading of drunkenness in the years 1910-14 was 193,354. The figure fell to 33,858 in 1932, but since then there had been a gradual rise to 48,110 for 1935, the last year for which figures were available. The number of persons received into prisons on conviction for drunkenness in 1913 was 52,149; in 1932 it had fallen to 5,836, but a slight upward tendency since then had to be noted, and in 1935 the figure was 6,880. The approximate number of drug addicts in the United Kingdom known to the central authorities in 1936 was 616, being almost equally divided between the sexes, and representing one in 76,000 of the population. Of this total 137 were said to be members of the medical profession.

Dr. East said that the curative value of imprisonment for drunkenness had probably never been convincing; at the same time persons addicted to alcohol no doubt derived benefit even from short periods of enforced abstinence. Prison medical practice necessarily afforded a large-scale experiment in the relation of the abrupt withdrawal of alcohol to delirium tremens. When cases were more numerous it was the general experience of prison medical officers that on persons verging on an attack of delirium tremens being received in prison, the enforced abstinence and medical care and treatment often shortened the attack; there was no reason to believe that recent experience pointed to a different conclusion. Abrupt withdrawal in cases of addiction to narcotic drugs was also the usual practice of prison medical officers, and the fact that the patient realized that he was under control and must face up to the situation had therapeutic value. Further, there was some reason to think that the sense of inferiority and

dependence in the addict was less pronounced in the prison hospital because he realized there that other patients were also social failures, and, like himself, must be re-adjusted to society.

International Conventions

Major W. H. Coles reviewed the advance in the control of the trade in narcotic drugs brought about by the Geneva Convention, 1925, which extended the import and export certificate system and set up the Permanent Central Opium Board. By these means discrepancies between the amount of drugs exported and imported were virtually eliminated—in other words, the escape of licitly manufactured drugs into the illicit market was prevented. This control was supplemented by the inauguration, through the Limitation Convention, 1931, of a complete system of limitation of manufacture of drugs to medical and scientific needs and the setting up of a body to supervise and if necessary to frame estimates of the drug requirements of all countries. Major Coles gave an account of the work of this supervisory body, and said that thanks to the stricter application of the international conventions there had been during the last few years a progressive shrinkage in the difference between the quantity of drugs manufactured and the quantity legitimately consumed. Statistics furnished by Governments showed that the amounts manufactured approximated more and more to the legitimate consumption, leaving little apparent margin available for the illicit market.

No precise knowledge was available of the amount consumed for the purpose of maintaining addiction, nor could any accurate estimate of the number of persons using drugs for that purpose be formed. It was certain that in some countries the number of addicts was very small and in others very large. In 1930 the Canadian authorities estimated approximately one addict in 1,000 of the population, and the United States reckoned a similar figure. In 1928 it was considered that the proportion of addicts in the large towns of Germany was one in 10,000, and one in about 18,000 elsewhere. In Egypt it was estimated in 1930 that the addicts numbered half a million in a population of fourteen millions, but this figure had been much reduced in later estimates, and in 1934 the Egyptian authorities reported some 18,500 addicts. The Chinese Government, in reply to a questionnaire addressed by the League of Nations, gave the number of registered opium addicts as 3,700,000. It had been stated that in Harbin there were no fewer than 300 heroin dens, besides 100 authorized opium saloons. No one knew how many clandestine factories there were, nor what was their output.

The next step in control, leading, it was hoped, to the ultimate elimination of illicit traffic, was the limitation of the production of the raw materials from which drugs were produced to the quantity necessary to supply the medical needs of the world. The preliminary work in connexion with this task was in progress.

CAUSES AND TREATMENT OF STERILITY

At a meeting of the West London Medico-Chirurgical Society on January 7, with Dr. G. RICE-ONLEY in the chair, a discussion took place on sterility or infertile marriage, its causes and treatment.

Mr. EARDLEY HOLLAND described a routine of examination and treatment which had been found successful in a certain number of cases. It began with an investigation of the history and a cursory gynaecological examination, following which the woman was given a prescription of thyroid gland in graduated doses. This first stage included an examination of the husband: he refused to have anything to do with the case unless the husband co-operated. The second stage of treatment, after three

brane nor by direct inhalation of spores into the lungs. Some patients had abdominal symptoms, which might be due directly to food, but sometimes were more complicated. A few had migraine, in which the cause of the trouble seemed to be either a food or a dust. All these conditions must depend upon local tissue sensitivity, and there was evidence that some organs and tissues were more sensitive than others. There was evidence also that the offending substance could enter the blood, and that helped to explain some of the remote symptoms. Deaths from asthma were uncommon, but a few had been reported. In a patient who had died of suffocation in an acute attack of asthma the lung was found to be studded with plugs of tenacious mucus. A series of hypertrophied and overactive mucous glands was also found in the wall of the bronchus. The real lesion in the lung was the hypertrophy and overactivity of these mucous glands, which continued to pour out a sticky material into the lumen of the bronchus. The mucous plugs would account for all the symptoms. They were not necessarily terminal appearances, but occurred in life, as he illustrated by lipiodograms of the lungs.

Treatment of Asthma

Professor L. J. WITTS said that the asthma problem was one of the most difficult in medicine. It was possible to desensitize those patients who were skin-sensitive, give vaccines to those who had infection of the bronchi, and in those numerous cases which showed neither of these phenomena various forms of non-specific treatment could be used. He recalled an important paper by Dr. Rackemann, who confessed that he thought he had cured a number of his asthma patients, but later discovered that the cure had not persisted. Some patients who had had one kind of sensitivity came back again with a different kind; to use Dr. Rackemann's expression, the gun had remained loaded though another trigger was now fired. He had found adrenaline and ephedrine useful, and it was worth pointing out that some of the most remarkable advances seen in medicine in recent years had been in respect of drugs which controlled abnormalities of muscle and secretion; he instanced ergotamine in migraine and prostigmin in myasthenia. The search for some general bodily disturbance which accompanied asthma seemed to him the most fundamental method of approach. Few of them believed that psychic causes were the principal ones, though they were impressed by the psychic factor.

Assessment of Results

Dr. E. R. BOLAND said that opinion differed as to whether medicine had any right to be complacent regarding the treatment of asthma, but the limitations of such treatment should at any rate be recognized. The fact that the assessment of the results of treatment was so difficult was a criticism of the therapeutic achievement. Superficially such assessment should not be difficult. The patient came for treatment, received it, and was better, going away loud in his praises. But if the physician had a sceptical streak doubts might well break through his self-satisfaction at such a result. The patient said that he was better, and by saying so he was better, but was there any objective evidence of real improvement? Such improvement as appeared might be due to chance or to the passage of time or change of season. If a patient really appeared to be cured he sometimes found that he had often been cured before, and if this time he remained cured the fact that allergic conditions not infrequently ceased of their own accord prevented the physician from feeling any real satisfaction. One had to beware of the personal good will of patients, and their anxiety to encourage the doctor by saying that a particular treatment had done them good, when in fact there was no objective evidence of such improvement. From a study of cases in the asthma research unit of which he was in charge

he had found it difficult to resist the conclusion that more than half the patients suffering from asthma showed improvement under general medical treatment alone, and if this was taken into consideration, as it must be, in the assessment of the results of specific treatment, much of the improvement which was at present credited to specific methods was not really due to them at all.

Psychological Factors

Dr. L. S. T. BURRELL thought that the psychological aspect of asthma had not received sufficient attention in the discussion, and he proceeded to describe a few cases in which this aspect seemed to be the important one. He remembered the case of a resident medical officer at a hospital who had an attack of asthma so severe that he was about to take to his bed when a telegram arrived announcing the death of his mother. He immediately got out his car and proceeded to drive the forty miles to her house. He had gone twenty miles when he suddenly remembered that from the time he received the news his asthma had totally disappeared. The recollection brought it on again, and he arrived at his mother's house almost in a state of collapse. Many years ago the speaker had an asthma clinic at Brompton Hospital, mainly for the treatment of children. Twenty years later, when he asked the lady almoner to look out the cases treated in that clinic, it was found that about 70 per cent. of them had "grown out of the asthma." There were patients whose asthma cleared up after an accident, and women who on becoming pregnant lost their asthma. He had in mind the case of one lady who for many years had been under treatment for asthma with no satisfactory result. She was injured in a motor-car accident, breaking several ribs, and from that time onwards she had no return of the trouble. He also mentioned the case of a woman who said she had an attack of asthma whenever she went to Waterloo Station; as she lived at Surbiton she had to go to Waterloo whenever she came to town. A certain amount of bluff was tried in this case. It was mentioned to the lady that some building work was proceeding at Waterloo and that she was no doubt sensitive to the brick dust. An injection of what she was assured was brick dust was administered, and she never had asthma thereafter!

General Discussion

Mr. FRANK COKE said that the claim of this country to be the first in the field of allergy rested on the extraordinarily accurate description by Hyde Salter of himself as a cat asthmatic—a description which could not be improved upon to-day, even though written seventy years ago. In the treatment of asthma an enormous advance had been made by the addition of adrenaline to the desensitizing doses of protein, thereby allowing much larger doses of the protein to be administered and the whole course of treatment to be speeded up. He also drew attention to the differential sedimentation test, by which an examination of the serum of a patient allowed the case to be placed into the allergic, microbic, or aspirin-sensitive group. The subdivision into these three groups allowed the effect of any one treatment, such as gold, to be tried and the results recorded. Work on allergy had rather overshadowed consideration of the bacterial types of asthma. Much attention was now being attracted to these types, and with success, so that even the aspirin-sensitive patient was becoming curable by vaccines made from organisms recovered from the nose and given in suitable doses. Dr. G. W. BRAY suggested that all protein foods, especially in allergic cases, were absorbed from the lymphatics of the stomach, passed direct through the thoracic ducts, and so into the lungs. Experimental findings, coupled with observations he had had the opportunity to make, seemed to point to the lymphatics as the primary route of absorption rather than the blood.

40.8 per cent. died. During 1936 at the Maudsley Hospital (where none but voluntary patients are treated) 959 persons suffering from early mental or nervous disorder were treated as in-patients and 3,811 as out-patients. A further 1,468 persons were treated as out-patients at psychiatric clinics established in association with the Maudsley at three of the Council's general hospitals north of the Thames. The total number of living mental defectives known to the Council at December 31, 1936, was 17,207, of whom 10,937 were under active care—a ratio of 4.16 per thousand of the population of the County of London.

Research on Mental Defect

On January 7 the board of directors of the Royal Eastern Counties Institution for the Mentally Defective, Colchester, entertained the members of the Darwin Trust to lunch at the informal opening of the research laboratories attached to the institution. Among those present were Sir Hubert Bond, Miss Darwin, Professor Adrian, Dr. Landsborough Thomson, and Dr. E. O. Lewis. Towards the cost of the building the Hon. Alexandrina Peckover contributed £2,200, the Hon. Lady Darwin £500, and it is hoped that other contributions will be received. The Rockefeller Foundation has given £700 and the Darwin Trustees £50 towards the cost of equipment, and the Rockefeller Foundation is making an annual grant of £600 for five years to provide additional research workers. Dr. L. S. Penrose, who is a member of the external scientific staff of the Medical Research Council, is directing the work. The permanent workers in the department are a social investigator, two laboratory technicians, and a biochemist. Attached to the department are Dr. Munro (Beit Fellow) and Mr. J. C. Raven (Medical Research Council grant). The building is single-storied, 77 ft. long by 40 ft. broad, on a site adjacent to Turner Village. It contains one laboratory suitable for biochemical and pathological investigations, another for microscopical work, a clinical room, dark-room for photography, three offices, testing-room, workroom, and lavatories. The heating and hot-water supply are provided by an automatic gas-fired boiler. Among the items of equipment is an electric calculating machine. A Medical Research Council special report, entitled "A Clinical and Genetic Study of 1,280 Cases of Mental Defect," which will give the results of the work of the last seven years, is to be published early this year.

The Welfare of Cripples

In its origin the word "cripple" meant "one who creeps," or perhaps, in the Scottish phrase, is "cruppen up," and the 1611 version of the Bible renders the phrase in the Acts of the Apostles "a creeple from his mother's womb." A revolution has taken place in crippleddom during the last generation, partly due to new orthopaedic treatment, and partly to a new care for the cripple from the social, educational, and vocational points of view. Special services for cripples are almost entirely a growth of the present century. It is true that a few institutions for cripples were established in the nineteenth century, and the first hospital reserved exclusively for orthopaedic cases, now the Royal Cripples Hospital at Birmingham, was founded as far back as 1817. But the first of the modern type of orthopaedic hospital was built in Cheshire in 1899 by the Royal Liverpool Children's Hospital to carry out the methods recommended by Sir Robert Jones, the pioneer of the new movement, and in the following year Dame Agnes Hunt founded the home at Baschurch which is now the orthopaedic hospital at Oswestry. All this and much more is described in the handbook issued by the Central Council for the Care of Cripples.¹ There are chapters on the discovery of the

cripple, by which is meant the search for those who are in need of orthopaedic treatment to prevent later crippling, the treatment of cripples when discovered, and their training and rehabilitation. The chapter on treatment is written for the layman, and is intended to give only a general idea of the treatment applied to orthopaedic cases, so that he may appreciate the reason why it is lengthy and the need for after-care. The considerable powers and duties of public authorities are clearly set out: extensive as these are, there is plenty of work remaining to be done by voluntary associations, and this is also described. The handbook gives some useful directions for the lay-out of an orthopaedic hospital, including the out-patient department and fracture clinic. The conditions which a rehabilitation centre should fulfil are noted. At present, while the treatment of injuries, restoration of function, and vocational training are provided to some extent at centres in different parts of England, there is still no provision for reconditioning, except for the small centre established by the L.M.S. Railway at Crewe. It is hoped that before long one such centre may be established on a large scale by way of experiment.

SCOTLAND

St. Andrews Institute for Clinical Research

The annual report of the James Mackenzie Institute for Clinical Research states that the institute has now accumulated a large number of records which promise to yield information of much value, and that the work of record-taking still goes on. During the year ended July, 1937, forty-eight new cases were taken and 806 notes were added to the existing cases. The annual classification of the records showed that 50 per cent. were complete, 22 per cent. required to be brought up to date, and 28 per cent. were incomplete, chiefly because patients had left the district. Periodic examination of children continued. Most of them had been under observation since birth, and in many instances the child's family and environment had been observed for a much longer time. Children were recalled to the institute for routine examination two or three times each year, while houses were visited and conditions correlated with those of the children. Early in 1937 a survey of congenital heart cases was started, and it was decided for control comparison to tabulate the case histories of some hundreds of children who had been observed from birth to about 10 years of age. This statistical survey is regarded as unique and capable of yielding valuable information. Since the foundation of the institute in 1919 the family doctors of St. Andrews have worked in full co-operation with the public health department in all activities affecting the well-being of the people, and the report considers that legislation shows a gradual trend "towards the creation of a system of public health administration similar to that in which has arisen out of Mackenzie's teaching." In the laboratory of the institute during the past year 693 investigations were carried out, and in the x-ray department 308 examinations. Various donations for research are recorded. The expenditure for the year amounted to £1,407, and the income to £1,039, but the funds still amounted to £14,870.

Scottish Universities By election

A writ for the combined Scottish Universities Parliamentary by-election caused by the death of Mr. Ramsay MacDonald is being issued this week. It will be a four-cornered contest. The candidates are the Right Hon. Sir John Anderson, lately Governor of Bengal, who is supporting the National Government as nominee of the Unionist Association of the Scottish Universities; Miss Frances Helen Melville, LL.D., late Mistress of Queen

¹ *Handbook on the Welfare of Cripples*. Published by the Central Council for the Care of Cripples, 34, Eccleston Square, S.W.1. (Is.)

months on thyroid, began with a more complete examination of the tubes, using lipiodol, which was much more reliable than insufflation. In a certain proportion of cases the lipiodol injection was followed by patency of the hitherto blocked tubes. The third stage of treatment was by means of hormones. In the large proportion of cases in which there was genital hypoplasia considerable doses of the follicular hormone might be given.

Correlation of Factors

Mr. KENNETH WALKER dealt with conditions in the male. He asserted that if it were possible to correlate all the factors in childless marriage it would generally be found that they were multiple, and that there were adverse factors on the side both of the male and of the female. He thought that the importance of such conditions as infection of the genital tract had been over-stressed in the past. Gonorrhoea, it was true, could produce absolute sterility, but in the usual cases of childlessness what was found was not absolute sterility but impaired fertility. Ten years ago in such a discussion he would have laid chief emphasis on local conditions; to-day he would lay chief emphasis on constitutional troubles. Endocrinology offered some hope, though he did not mean that every case was due to dysfunction of the endocrine glands.

Mr. V. B. GREEN-ARMYTAGE suggested that it was important that medical officers and matrons of girls' schools should carefully observe the time of onset and type of menstruation. Hypoplasia did not begin at the age of 25 when the woman came to the gynaecologist, but it began in early youth, and if care were taken at that period as to diet, exercise, and the giving of oestrogenic substances when necessary subsequent infertility might be lessened. Mr. Green-Armytage was convinced that contraceptive measures in the early days of marriage were inimical to pregnancy at a later date. He showed lantern slides of lipiodograms taken in various types of cases. Salpingography was carried out as a routine on the Continent, and if general practitioners realized its ease and painlessness more of these cases would be investigated. It had the advantage over insufflation in that it gave information as to whether both tubes were patent or only one, and whether there was any abnormality in the uterus.

Dr. F. J. McCANN referred to the importance of preventing certain childish ailments, which left a far more important imprint than was generally realized. Many of the exanthemata and other acute diseases of early life caused vulvo-vaginitis, forming adhesions, but they also left their mark on the ductless glands, and the result was seen only after puberty. Irregularity of menstruation in the young girl should be looked upon as a serious condition demanding treatment, the treatment being first diet, secondly exercise, and thirdly appropriate medication. Dr. McCann added his strong belief that contraceptive measures did delay fertility for a considerable time, and might cause sterility.

Others who participated briefly in the discussion were Dr. MALCOLM DONALDSON, Mr. G. J. SOPHIAN, and Dr. VAUGHAN PENDRED.

From recent reports in the Press supplied by Reuter it appears that Sister Elizabeth Kenny, whose methods of treating anterior poliomyelitis form the subject of an article by Dr. F. H. Mills at p. 168 of this issue and are commented on at p. 178, has been asked to supervise a test of her treatment which is to be carried out by the Government of Victoria. In the epidemic of poliomyelitis which is at present causing concern in Victoria, 1,600 cases and eighty-seven deaths have been notified up to the end of December. Twenty-two hospital beds have been placed at the disposal of Sister Kenny, and the results of her treatment will be watched by a medical panel which is to be set up by the Victorian Branch of the British Medical Association.

ENGLAND AND WALES

The Tuberculosis Problem in Wales

The Government inquiry into the new scheme of the Welsh National Memorial Association for combating tuberculosis in Wales opened at Cardiff this week, when Cardiff Corporation and several of the Welsh county councils raised objections to the estimates of the Association on the ground that they would cause an unjustifiable increase in expenditure during the next five years. The Memorial Association proposes a capital and extraordinary outlay of nearly £400,000 on hospitals, clinics, and sanatoria. The Cardiff City Council objects that items are introduced involving financial principles to which it declines to contribute. In its opinion the new hospital at Swansea, which the Memorial Association proposes should be built at a cost of £200,000, is not justified by the circumstances. It also takes exception to the basis of contribution, and argues that during recent years the increase in expenditure to combat tuberculosis in Wales has been out of all proportion to that of other health services. A statement prepared by Lord Davies, president of the Memorial Association, was read to the Committee of Inquiry before evidence was taken. The whole of the first day's session was given up to an examination of a long memorandum setting out the history and achievements of the Association and its recommendations.

L.C.C. Mental Health Services

Vol. VI of the Annual Report of the London County Council for 1936¹ deals with the administration of the Council's mental health services during the year ended March 31, 1937. On the last day of 1936 the total number of patients for whom the Mental Hospitals Committee was responsible was 38,282. The average annual increase in the number of mental patients for whom institutional care has been provided since 1920 was 584. The need for accommodation for persons who are mentally disordered is approximately in the ratio of 3 male beds to 4 female beds. The number of cases of mental disorder receiving institutional treatment shows a ratio of 6.62 per thousand of the population of the County of London. Nearly 70 per cent. of the direct admissions during 1936 were first attack cases, and prolonged mental stress was deemed to be the principal cause of mental breakdown in 520 of the 3,437 cases admitted directly. The total number of patients readmitted during 1936, after having been previously under treatment as certified, voluntary, or temporary patients, was 753, representing 21.2 per cent. of the total number of admissions. At the London County mental hospitals 11.27 per cent. of the certified patients were allowed parole in the hospital grounds, and 3.45 per cent. were permitted to be on parole outside the grounds; 11.90 per cent. were granted short periods of leave up to four days. An experiment is being made at one hospital to provide a few suitable voluntary patients, after recovery, with special training at educational institutions in trades for which they appear to have taste or aptitude in preference to some uncongenial form of prior employment, so that they may be able to take their place in the outside world again with a better chance of success and with less risk of a further mental breakdown. Some interesting figures are given relating to general paralysis of the insane before and after the commencement of the treatment by induced malaria. During the six years 1908-13, of the total number of such cases under care only 1.49 per cent. were discharged and 79.92 per cent. died, whereas during the six years 1930-5, 19.8 per cent. were discharged and only

¹ P. S. King and Sons, Ltd., 14, Great Smith Street, S.W.1. (Is., post free 1s. 2d.)

principle to meet the supposed needs of their prospective juvenile occupants, and the domestic staff having been promoted wholesale by the simple device of putting them into nurses' uniforms, nothing remains save to advertise widely and wisely. The former Minister of Public Health, M. Sellier, was so impressed by what he learnt of the activities of these mushroom institutions that he issued a circular on the subject in April, 1937. According to this circular "preventoriums" should be classified according as they belong to one or other of three well-defined groups. To belong to the first a children's "preventorium" has to be provided, among other things, with a resident medical officer, x-ray apparatus, a laboratory, and hospital beds; third-group institutions must provide sufficient material comfort, proper surroundings, and plenty of good food. At the present time the prefects throughout France are completing a survey of the children's "preventoriums" within their jurisdiction, and when their findings are available it is to be hoped that the selection of temporary homes for delicate, sick, or convalescent children will be made with more discrimination than has hitherto been possible.

Professor René Leriche

It will be remembered that the last occupant of the chair of medicine of the Collège de France was the late Professor Charles Nicolle. The Academy of Sciences, whose duty it is to recommend candidates for this vacancy, has headed its list with Professor René Leriche of Strasbourg. His work on the sympathetic nervous system, not to mention several other activities, earned him an international reputation many years ago, and his treatment of recent sprains by the prompt injection of local anaesthetics has attracted considerable attention. To epitomize the guiding principle of his career one might say he has made surgery the efficient servant of physiology.

"Perhaps" Surgery and the Forty-hour Week

When Dr. Georges Duhamel, literary star and ex-surgeon, addressed the Academy of Medicine on December 7 on the application of the forty-hour week to the Paris hospitals he created quite a sensation by the picture he drew of the demoralization which he believed had followed the application of this measure. With the operating theatre staff replacing each other at comparatively short intervals, surgeons, he said, would be informed that such and such an instrument just about to be used was "perhaps" sterilized. Much of the rest of his address was in the same strain. It quickly became a political issue in the lay press. On December 21, before the same forum, a vigorous counterblast came from no less a person than M. Mourier, who is at the head of the Paris Assistance Publique, responsible for 42,000 hospital beds. The gist of this counterblast was that if Dr. Duhamel had painted a true picture the new law would be reflected in a rise in the hospital mortality. In 1936, before the introduction of the forty-hour week, there had been 157,930 admissions and 11,879 deaths. In 1937, after the introduction of the forty-hour week, there had been 158,610 admissions and only 11,763 deaths. In other words, during the first seven months of the new law the hospital death rate had gone down, not up. Another of M. Mourier's points was that an inquiry instituted in most of the Paris hospitals since December 7 had shown that the patients received just as good treatment in the operation theatres as before. He added that no surgeon had reported to him any fatal lapse due to the new law. To which Dr. Duhamel retorted on the same occasion that the problem was not yet one of mortalities but of moralities. He added that the correspondence he had received from hospital physicians and surgeons in Paris and the provinces constituted a dossier whose cumulative effect was undeniable. Who is telling the truth? Both, surely, but slightly divergent aspects of it.

Correspondence

Pasteurization of Milk

SIR.—Dr. Norman Macfadyen's letter in your issue of January 15 (p. 148), coming from one who is not only a member of a local authority but a medical man, may be expected to carry some convincing weight. It is therefore to be assumed that in considering the matter in both capacities he has weighed every relevant factor before expressing himself so definitely in print. He makes no mention, however, of the effectiveness or otherwise of correct pasteurization in minimizing the risk of the organism of tuberculosis reaching the consumer. He has not said, in defence of "T.T." milk, what it could have done to prevent a communal tragedy such as occurred in this district in 1936: or others of the hundred or more outbreaks of infectious illness, streptococcal and otherwise, which have been recorded since 1912 in this country attributable to infection from raw milk, and which were in so many instances effectively checked by pasteurization.

May I refer Dr. Macfadyen to the most recent summary of available knowledge on milk generally in "The Milk Problem" (*Bulletin of the Health Organization of the League of Nations*, vol. vi, No. 3, June, 1937), and draw his and other troubled spirits' attention in particular to such references as on page 49—"Great Britain: *Brucella abortus*: milk from tuberculin-tested herds affords no exception, and as many as 74 per cent. of samples have been found infected"; on page 75, "So far from there being antagonism between pasteurization and clean milk production, there should be a very close association," and, "It is now abundantly clear . . . that milk treated by holder pasteurization . . . in properly designed and efficiently operated plants is free from living tubercle or *abortus* bacilli"; on page 79, "The provision of a safe milk supply to the human population is essentially a public health problem and can be solved satisfactorily only by compulsory pasteurization."

It is perfectly true that extracts apart from the whole context may put fallacies in the path of argument. I would, however, assure Dr. Macfadyen that my concern has been, first, to conserve the space of the *Journal*, and, secondly, to stimulate Dr. Macfadyen's enthusiasm to the extent of reading the whole illuminating and critical study to which I refer above.—I am, etc.,

R. J. MAULE HORNE.

Public Health Department, Poole, Jan. 15.

SIR.—Dr. Norman Macfadyen may be justified in his claim that "our certified T.T. milk" at Letchworth has produced better results than its local rivals. He must, however, be well aware that a supply of T.T. milk anything like adequate to meet the needs of the community is impossible, for the very sufficient reason that the herds to produce it do not exist, and, at the best, cannot exist for many years. Hence even if his prescription for the admitted ills of the milk supply is allowed to be theoretically effective, it is none the less useless as a practical measure.

Meanwhile, raw milk as distributed to the community contains in some 5 to 10 per cent. of the specimens examined living tubercle bacilli, and is, as recent events have illustrated, an agent in the distribution of epidemics of certain acute infectious fevers, while efficient pasteurization prevents these mischiefs and leaves the nutritive qualities of the milk practically unimpaired.

Margaret College, University of Glasgow, who is standing as an Independent; Professor A. Dewar Gibb, who holds the regius chair of law in the University of Glasgow and is standing as representative of the Scottish Nationalist Party; and Sir Peter Chalmers Mitchell, LL.D., D.Sc., F.R.S., who was adopted as Independent Progressive candidate at a meeting of Scottish graduates held in London last week. Sir Peter retired from the secretaryship of the Zoological Society of London in May, 1935; in earlier life he was for some ten years lecturer in biology and examiner in zoology at London University and the Royal College of Physicians. At his nomination meeting he declared himself an advanced left-wing progressive, a democrat who believed that any stable structure of society must be based on the will of the people expressed in complete freedom of religious and political opinion with equality of sex and race.

Training in Psychiatry

Dr. I. M. Sclare, consulting psychiatrist to the Public Health Department of Glasgow, recently addressed the Scottish Association for Mental Welfare on the subject of "Psychological Illness." He said that psychological disorders were evidenced by various disturbances of function, and might affect any organ of the body, even when the patient did not suffer from a specific bodily condition. Many thousands of people suffered from functional illness without any mental disorder, and some of these had a great dread of insanity. Psychological illness, moreover, should not be regarded as a halfway house between physical and mental disturbances, for functional illnesses often occurred in people of superior mental and physical attributes. The prevalence of this type of illness had been variously estimated to be the fundamental factor in from one-third to three-fourths of all sickness. The serious aspect was that the patient was deprived of his potential value to the community, and his illness might be unconsciously imitated by his children in later life, impairing them emotionally or intellectually. Crime, delinquency, and political extremism might be the ultimate result of such a condition. Medical students, he held, should be taught in a course of psychiatry to detect the psychological factors in all illness, and to recognize the need for specialist treatment when confronted by difficult problems. Doctors would then have a better understanding of their patients, and hospitals would be considerably less congested, while psychiatric clinics would spring up where functionally sick persons would willingly go for treatment.

The Nursing Problem

At the annual meeting of subscribers to Stirling Royal Infirmary an address was given by Miss F. N. Udell, organizer for Scotland of the College of Nursing, in which she said that they were faced with an acute problem in the grave shortage of suitable candidates for the nursing profession. It was sometimes stated that this was because conditions were bad, hours of work long, and nurses were treated like slaves; but nurses themselves did not think that these were the reasons. It was not proved that there was any decrease at the present time in the number of candidates coming forward; the shortage was really due to the tremendous extension of nursing services throughout the country. Figures recently collected showed that during the last ten years, in four of the large hospitals of Scotland alone, 300 additional nurses were required each year. In pre-war days, if a girl wanted to take up professional work she had practically to choose either nursing or teaching; to-day there was virtually no profession that a woman might not enter, so that nursing was now in competition with all the other professions open to women. With regard to nurses' hours, this question could not be dealt with by rigid legislation; there were emergencies which, every nurse of experience would admit, might make it necessary to work longer hours. The work

of the nursing profession was not going to be served in the best way if it was reorganized by outside bodies knowing nothing of the rather peculiar difficulties that the profession had to meet. The speaker appealed to the public to recognize as much as they could the difference between a trained nurse and other persons who called themselves nurses. They wanted to educate the public and the medical profession to the fact that nurses were now State-registered, and that untrained women were not serving the best interests of the profession. Dr. P. F. McFarlan said it was admitted that nurses had long hours, but these hours were shorter than they used to be. Complaints were sometimes made that discipline in hospitals was too severe, but discipline was necessary if nurses were to be properly trained for their duties in life, and hardship in the nursing profession was not overwhelming during training. The superannuation scheme which had lately been started by the College of Nursing ought to be made universal and interchangeable between all hospitals. It was, he thought, little short of a catastrophe that a regulation of the profession of nursing should tell a probationer on the threshold of her career that she should not work more than forty-eight hours in a week.

FRANCE

[FROM OUR CORRESPONDENT IN PARIS]

Freak Deaths

Several correspondents have lately exchanged experiences in that admirable fortnightly journal *Le Siècle Médical* with regard to freakish and often disconcerting deaths among their patients. The best story of the bunch is that told by Dr. Parrique, who in any but a highly respectable medical journal would be suspected by his readers of romancing. Some years ago he was called to a patient suffering from a bulky pleural effusion on the left side. The heart was displaced, dyspnoea was severe, and the patient was cyanosed. Aspiration seemed urgently indicated, so he thrust an artificial pneumothorax needle into the chest. Before he could withdraw the stylet and proceed to aspiration the patient collapsed and died within a second of the puncture, which was made in the customary position at the back of the chest. Three hours later he was called to a very similar case, and the patient's death at the moment of introducing a needle into his chest was as prompt and spectacular as in the first case. In the evening of the same day the really rather unfortunate Dr. Parrique was summoned to a third patient suffering from heart disease and a large bilateral hydrothorax. It is easy to understand the hesitation to which he confesses. But after all puncture seemed to be the only rational method to relieve the patient's distress, and Dr. Parrique had just steeled himself to do his duty and defy fate when the patient suddenly died before even his skin had been pricked—*Lex coincidentiae!*

Massive Hospitalization of Children

The comparatively young and still potentially fertile national sickness insurance in France has resulted in a prodigious crop of hospitals, convalescent homes, "preventoriums" *et hoc omne genus* for children. What has been lacking in quality has been more than made good—or bad—by quantity and, above all, by variety. The owners or tenants of buildings ranging from mansions to bungalows and huts have obeyed the call of profitable altruism and have turned them overnight into nursing homes, convalescent homes, etc. In catering for children it is apparently quite easy to turn a drawing-room into a modern nursery by plastering the walls with childish pictures and spraying the floor with toys. The other rooms of a house having been "converted" on the same

referring to circumscribed glands which can be felt with the fingers but to a diffuse enlargement of the anterior triangle of the neck which is visible. All other forms of tonsillitis which may resemble diphtheria either never cause swelling of the neck or only do so after many days.—I am, etc.,

Reigate, Jan. 11.

HAROLD J. FARDON.

Lymphangioplasty

SIR,—My attention has been drawn to the interesting article on lymphangioplasty by Mr. Harold Hartley and Dr. R. A. Kemp Harper in your issue of November 27 last (p. 1066).

It is some testimony to the vitality and value of my operation that thirty years after its introduction it is the subject of an article in your columns, and that I have recently been asked to write a chapter on the subject for an American book. My own opinion on the operation as regards the lower extremity is that it has been superseded by Kondoleon's operation of fenestration of the deep fascia, which gives the lymph of the superficial tissues access to the subfascial (muscular) tissues where the lymphatic vessels are usually intact and able to absorb it. The valves of the deep lymphatics combined with intermittent muscular contractions form a pump mechanism which can overcome the action of gravity. In lymphangioplasty no such pump action comes into play, and gravity in the lower limb is too powerful to be overcome by the wick action of the buried silk threads.

For these reasons, while congratulating Mr. Harold Hartley on the brilliant success of his case, I am half inclined to agree with his modest conclusion that his operation had nothing to do with it. But such a verdict is against the weight of the evidence, for after the operation the condition of the patient, previously static or deteriorating, steadily improved. Mr. Hartley fails to consider the possibility—a very important one—that the operation may in favourable cases exert a permanent effect by breaking a vicious circle. When a tissue is in a state of solid oedema the pressure upon the veins of the exuded fluid, and of the fibrous hypertrophy which follows, must greatly increase transudation and so continually aggravate the oedema. If by silk drainage this pressure is relieved, even if only temporarily, transudation from the blood vessels will decrease, pressure upon any remaining patent lymphatics will diminish, and the "vis medicatrix naturae," to which Mr. Hartley gives all the credit, may complete the good work by the formation of new lymphatic vessels.

Dr. Kemp Harper's radiological evidence shows that silk threads may remain unabsorbed in the tissues for twenty-four years "without causing the slightest trouble," and is good criticism of Madden, Ibrahim, and Ferguson's conclusion that the wick action of the silk would soon cease owing to absorption of the silk. Madden's conclusion that silk as soon as it became encysted by fibrous tissue would lose its wick action is a pure hypothesis.

Let us now consider the upper extremity. Broadly speaking, the operation is only required for severe brawny oedema of the arm due to breast cancer. It must only be used for carefully selected cases where pressure on nerves is not present, where the threads will not have to pass through cancerous tissue, and where pleural effusion is absent. In such cases lymphangioplasty gives immediate relief from pain and restores the use of the arm for a period determined by the intrathoracic progress of the disease. The period may be short, but even so the relief is precious. It may be as long as five years. In these cases Kondoleon's operation is inapplicable, since all the

lymphatics round the shoulder-joint, deep as well as superficial, have probably been reduced to solid fibrous threads by permeation.—I am, etc.,

London, W.1, Jan. 14.

W. SAMPSON HANDLEY.

Lower Abdominal Pains of Cervical Origin

SIR,—Professor James Young, in the *Journal* of January 15 (p. 105), has described a fairly clear-cut syndrome due to disease of the cervix—namely, the type of chronic cervicitis associated with retention cysts. He states that by treating such cases by dilatation of the cervix, radial cauterization, deep puncture with the electric cautery, and the evacuation of the gland cysts, he obtained cure or partial relief in about 80 per cent. In a number of unsuccessful cases a second operation produced relief. In other words, the proportion of successful cases (especially when one considers the type of patient) is, I think, creditably high. Despite this, Professor Young now combines these simple and harmless procedures with nerve blockage of the inferior hypogastric plexus, using 85 per cent. alcohol, or, more recently, procaine.

The technique of alcohol injection of Frankenhäuser's plexus was ably described by A. A. Davis in the *Lancet* (1936, 1, 80), but Davis limited himself to the injection of but 1 c.cm. of alcohol on each side. It would be interesting to know whether Professor Young has seen any bladder complications following the much larger amounts that he uses. What I am still more concerned about is the possibility of such injections producing a pathology of their own. It is a regrettable fact that the exhibition of alcohol invariably produces tissue damage, with subsequent fibrous-tissue replacement. A fairly large experience of intrathecal injections of absolute alcohol for the relief of severe pain associated with cervical malignancy has made me chary of using alcohol, because I have now obtained histological proof that degenerative changes follow in the posterior nerve roots and the posterior columns of the cord adjacent to the site of injection. Recently other observers have reported similar findings. In consequence I feel that one should restrict such therapy to patients with a limited expectation of life, and I ask whether alcohol injections can safely be given into the base of the broad ligaments? It would be of interest to learn whether Professor Young knows of any late sequelae such as intractable neuritis or ureteral obstruction. I have been much struck by the frequency of ureteral obstruction in association with parametrial fibrosis, and presumably such injections, which are given in close proximity to the ureter, might be productive of similar late effects.

The biggest stumbling-block with all such therapeutic measures is undoubtedly the fact that we are largely dependent on subjective phenomena for our deductions. When dealing with severe and intractable pain the necessity for morphine, the prevention of sleep, and the willingness to undergo major operative procedures provide us with criteria which, to a certain extent, allow scientific deductions to be made. In the type of case discussed by Professor Young these criteria are not to hand, and in consequence it is extremely difficult to make observations carrying scientific weight. Personally, I think that the impracticability of obtaining sufficient comparable controls in which some of the known accessory (if not precipitating) factors can be adequately supervised is an almost insuperable difficulty. This type of case will continue to furnish us with an infinite variety of impressions, the effectiveness of any particular line of therapy being camouflaged by factors beyond our control, such as the family budget, coitus interruptus, or domestic upheavals. As a corollary, successful therapy will be associated very largely with the

The discussion of an ideal non-existent milk supply may be an interesting exercise in rural retreats, but in the world of practical affairs the choice, in fact, is between a safe and an unsafe milk supply. To the consideration of safety Dr. Macfadyen does not seem to have applied his mind. Everyone would agree that milk should be pure—that is, free from adulterants—and clean—that is, free from dirt; also that its bacterial count should not be excessive. Surely, however, it is particularly the responsibility of the medical profession to insist that milk should be safe—that is, free from the risk of communicable disease. Such representative medical organizations as the Royal College of Physicians, the British Medical Association, and the Joint Tuberculosis Council have publicly and repeatedly recognized this obligation, and have urged the protective value of pasteurization in the general interest. Dr. Macfadyen finds this policy a “cunning” attempt to influence public opinion. The original meaning of this adjective I take to be “kenning” or “knowing,” and in this sense the term may be accepted as a compliment. Later and perhaps more common meanings include such equivalents as “artful,” “crafty,” and “sly,” and I am sure Dr. Macfadyen would not so label the activities of his professional colleagues. These activities, I agree, are based on “knowing,” and Dr. Macfadyen is good enough to say so.—I am, etc.,

London, Jan. 17.

C. O. HAWTHORNE.

Gastro-enteritis due to *Bact. sonnei*

SIR.—In the third paragraph of his interesting paper on Sonne dysentery (*Journal*, January 8, p. 64) Dr. Reginald Miller makes two statements about the so-called epidemic gastro-enteritis with which I cannot altogether agree—namely, that it is essentially a summer disease and strictly confined to infants. Epidemic gastro-enteritis is, of course, an ill-defined condition, and doubtless Dr. Miller refers to the disease, if such it can be called, known formerly as summer diarrhoea. This was endemo-epidemic in type, with large summer outbreaks attended by a high infant mortality. But the cases were, and still are, by no means confined to children. O. H. Peters, in a masterly field study entitled “Observations on the Natural History of Epidemic Diarrhoea” published in the *Journal of Hygiene* for 1910 traced the infection of fatal cases in children to mild cases in adults. For example, some signalmen working in the same signal box, and infecting each other with diarrhoea, conveyed the infection to the children in their own homes situated widely apart.

The summer epidemics were shown by a number of observers to be due to fly-borne infection. With the increased control over the breeding places of flies the time of the seasonal outbreak has become later in the year, and the greatly reduced peak now commonly falls in October. In some years the maximum number of deaths from “gastro-enteritis” occurs in the first quarter of the year. This winter peak is clearly not due to a specific infection, being secondary to droplet-borne respiratory infections, often associated in young infants with mastoid disease. Outbreaks of Flexner dysentery, as Dr. Miller points out, cause fatal cases in older children. From time to time a family outbreak of this disease occurs in Liverpool and fatally affects children of 2 to 5 years of age; a clinical diagnosis of Flexner dysentery has always been confirmed by bacteriological examination. To what extent the disease known formerly as summer diarrhoea was caused by the *Bact. sonnei* is a matter for conjecture. Examination of material from cases of infantile diarrhoea

has not, in Liverpool, shown any large proportion of Sonne infections. On the other hand, a recent outbreak of mild diarrhoeal infection on a training ship revealed a number of cases of this type among adolescent youths.—I am, etc.,

Liverpool, Jan. 11.

C. O. STALLYBRASS.

Use and Abuse of Antiseptics

SIR.—Professor Alexander Fleming in his letter under the above title in your issue of January 15 (p. 141) compares the effects of acriflavine on leucocytes and bacteria *in vitro*. The experiments are cited presumably in order to suggest that such antiseptics cannot be efficacious in combating infections. The general question is discussed in my Cameron prize lecture.¹ Here I shall refer only to two sets of conclusive experiments carried out on infected animals. In the first the infection of recent wounds in guinea-pigs was cured by the brief application of acriflavine²—mere washing with hypertonic or isotonic saline was ineffective. Secondly, infection of the peritoneal cavity in mice with virulent streptococci was cured by the subsequent injection into the peritoneum of acriflavine or certain anilquinoline antiseptics of the series to which quinamil belongs.³ In the last case it has been established that the therapeutic effect was not due to the rapid killing of the organisms by the antiseptic, but that cure was brought about by the co-operative action of the drug and the natural tissue defences. The effort to prove by *in vitro* tests that a chemotherapeutic agent cannot cure an infection when it actually does bring about cure in the living body reminds one of the conception of a tragedy attributed to Herbert Spencer—namely, a beautiful deduction slain by an ugly fact.

As to sulphanilamide, the rationale of its remarkable action in generalized experimental streptococcus infections is by no means elucidated as yet.—I am, etc.,

Glasgow, Jan 15.

C. H. BROWNING.

Early Diagnosis of Diphtheria

SIR.—As medical officer of a provincial isolation hospital I am greatly concerned at the delay in sending cases of diphtheria into hospital. Every practitioner should be aware that in any virulent case of diphtheria in which the patient is not producing his own antitoxin serum must be administered on the first or second day of the disease in order to save life. Yet there are still many practitioners who do not regard these cases as urgent.

Any virulent case of diphtheria can easily be recognized clinically on the second day. The swelling of the neck alone tells the tale. There is no other form of sore throat which produces a diffused swelling of the glandular and periglandular tissues of the neck by the second day of the disease. Every case of diphtheria which, if not treated, is virulent enough to prove fatal will reach the “bull-neck” stage by the fourth day, and the early stages of that “bull-neck” appearance are quite recognizable on the second day. If every practitioner who is called in as early as the second day to a case of diphtheria would recognize this diagnostic feature of the disease and realize that this is an indication for immediate administration of at least 40,000 units of antitoxin many lives would be saved. To take a swab and await the result in cases of this sort is to throw away a life. I am not of course

Insulin for Local Sepsis

SIR.—No doubt Mr. Nevil Leyton will proceed to test the efficiency of insulin in the treatment of chronic local sepsis in a variety of ways, but I trust that if he adopts the suggestion made by Dr. R. D. Lawrence—namely, that "one half of the wound should be dressed with active insulin, the other with heated—and so inactivated—insulin solution"—he will be careful to satisfy himself that the insulin he uses is really inactivated. If he simply boils a therapeutic solution of insulin it is doubtful whether its activity will be destroyed. Cheadle autoclaved insulin at 125° C. for twenty minutes at pH 2 and found the loss of activity was 20 per cent., whilst at pH 4 the loss of activity was much greater. Ordinary insulin solution has a pH 3 to 3.5, and therefore just boiling the solution would probably reduce its activity by less than 50 per cent.

Although it appears unlikely that insulin can have any local action even when the sugar content of the skin is above the normal—a condition which may exist without hyperglycaemia—nevertheless it is far from impossible. A number of years ago an attempt was made in my wards to determine the relative efficiency of horse serum and weak lactic acid in chronic ulceration of the skin. Horse serum contains a substance which neutralizes the proteolytic ferment liberated by the leucocytes; lactic acid hinders the activity of the ferment, which works best in a slightly alkaline solution. I reluctantly came to the conclusion that horse serum was the more efficacious. Insulin is destroyed by this proteolytic ferment, but its destruction may be accompanied by fixation of the ferment. If insulin proves to be really beneficial the cost should not be prohibitive. Pure dry insulin can be produced at less than threepence per hundred units, and sterilization, standardization, and various other tests would not be necessary for a preparation for outward application.—I am, etc.,

London, W.1, Jan. 15.

O. LEYTON.

Lymphoid Tissue of the Alimentary Canal

SIR.—With reference to Mr. H. Gordon Thompson's recent article on the lymphatics of the alimentary canal (*Journal*, January 1, p. 7), it would be of interest to know whether there is any great increase in the number of cells migrating through the intestinal wall from other parts of the intestines at the same time as, or a short time after, the migration occurs from the appendix. If there were an increase, it would prove that such migration was not only a local defence reaction, but that either by direct connexion through the lymphatic system or by other intermediate means there was a protective stimulation. I, personally, do not expect this to be the case.

It would be interesting to decide by further experiments whether the lymphocytes secreted into the intestinal tract contain antitoxic or bacteriolytic ferments which they did not possess before the invasion of the appendix by pathogenic organisms. This could be proved by incubating the secretions of the appendix which contain lymphocytes before and after inoculation with different quantities of pathogenic organisms. If an increased autolysis of the bacteria or an increase in the antitoxic substances could be demonstrated, it would mean that we have in this lymphatic tissue a highly effective general intestinal defence mechanism. This would explain the value of oral vaccine therapy, and it would also explain why, after a certain time, toxic organisms in the intestines disappear from them, as in typhoid fever, though they

are still present in other parts of the body. If one takes into account the much larger number of lymphocytes than that usually accepted secreted into the intestinal lumen, which was proved by the author, one can understand that such a general intestinal purifying action is possible from a comparatively small amount of lymphatic tissue. The reason why comparatively few lymphocytes are found on examination of the bowel contents is probably that these cells exert their destructive action by autolysis.—I am, etc.,

Bristol, Jan. 9.

ERNST PHILIPP.

Treatment of Pneumonia

SIR.—We have waited so long and patiently for a really satisfactory serum treatment for pneumonia that it was very depressing to learn from the leading article in the *Journal* of January 8 (p. 76) that another long wait may be before us whilst a new serum prepared from the blood of rabbits is being tested.

For this reason may I be allowed to break a silence that has lasted for eleven and a half years by referring to a treatment I introduced for pneumonia in a paper I was privileged to publish in this *Journal* (1926, 2, 109) under the title of "The Thyroid and Manganese Treatment"? First, may I remark that the observations and results therein recorded came from the practices of four colleagues with whom I had been working, as well as my own, and that they represented what all of us had learnt from the first forty cases that underwent the treatment. It was with their knowledge and consent that the paper opened with these words: "How has it become possible to state categorically, and with no fear of contradiction, that ordinary pneumonia, unaccompanied by intercurrent affections or occurring at too advanced an age, is one of the easiest diseases to arrest and cure?" Now as this statement has remained uncontradicted since the day it was made and observers in New Zealand, Australia, and America have published evidence in support of the opinions they hold with regard to the treatment's specific action in all types of pneumonia, and as Dr. Max H. Weinberg of Pittsburg proved that a cerebrospinal fluid that was teeming with pneumococci in a moribund case of pneumococcus meningitis Type III became sterile after forty-eight hours' application of this treatment (*J. nerv. ment. Dis.*, 1931, 74, 38), perhaps others may find some use for it while waiting for the serum treatment to arrive.—I am, etc.,

HERBERT W. NOIT, M.R.C.S., L.R.C.P.

Guildford, Jan. 10.

Correct Footwear

SIR.—I have been following with interest the correspondence on correct footwear. It is indeed a field for preventive medicine. No one so far has complained about heels. I suppose the previous correspondents have never had to suffer from the sort of heel that is put on to "smart" women's shoes. High heels seriously impair that flexibility of movement which I believe is necessary to foot health. I suppose they were invented because raising the heel foreshortens the foot and makes it look smaller as well as giving the appearance of a higher instep. I believe a heel is a disadvantage rather than a necessity. I suffered from metatarsalgia and tried various kinds of shoes and pads without much benefit until I came across a firm which makes shoes without heels and with a straight inner border. These seem to me as anatomically correct as any shoe can be. Unfortunately

personality of the individual doctor. In the present instance I would plead for the restriction of treatment to the simpler measures advocated by Professor Young—namely, dilatation of the cervix combined with thorough cauterization. To quote Professor Young's own *obiter dicta*, "In a large proportion of cases treatment of a simple nature directed to the underlying lesion is strikingly successful."—I am, etc.,

Manchester, Jan. 16.

T. F. TODD.

Shortage of Calcium in the Diet

SIR,—In discussing the alleged shortage of calcium in the "poorer-class" diet, Dr. Katharine Coward and her co-workers (*Journal*, January 8, p. 59) arrive at the startling conclusion that the child receives only 430 mg. of calcium while his daily requirements are 900 mg. But surely this amazing discrepancy arises in large part from the manner of calculation. The calcium content of the child's diet has been calculated from the analysis of the basal diet fed to rats—a basal diet to which was added in some groups of animals either calcium or milk. This diet contains almost no dairy produce, yet more than 55 per cent. of the calcium intake is derived from this source in the diet even of the poorest (Cathcart and Murray, *Med. Res. Council Rep.*, No. 218, 1936). In the diet of the poor child milk, and very often cheese, are included, the amount of the former being commonly augmented by free distribution in schools.

Accepting the figure of 430 mg. as the calcium content of the diet excluding dairy produce, it will be noted that the addition of three-quarters of a pint of milk alone would bring the figure up to 900 mg. Although it is admitted that all "poor" diets tend to be deficient in calcium, it seems to me that Dr. Coward and her co-workers in the experiments described have not established conclusively that there is a "serious shortage of calcium in the mixed 'poorer-class' diet." A fairer conclusion might be that milk and dairy produce, such as cheese, are desirable in larger quantities in the diet—a point which was urged by Professor E. P. Cathcart in the recent Hastings Lecture. Incidentally, the determination of the mineral needs of a relatively slow-growing organism like the child from experiments on a rapidly growing animal like the rat seems to be fraught with danger.—I am, etc.,

Glasgow, Jan. 10.

IAN MURRAY.

Treatment of Burns

SIR,—I have read profitably Mr. Mitchiner's article on the treatment of burns and scalds in your issue of January 1 (p. 27). I had been of the opinion that drastic mechanical cleansing of these injured areas under such light anaesthesia that it could scarcely be termed anaesthesia contributed largely to shock, and that loss of tissue fluids, dirty bacteria-laden fluids, in the first twenty-four hours after such accidents, as opposed to absorption, was desirable and therefore not a contributory factor to the mortality.

Noting Mr. Mitchiner's preference for a weak tannic acid solution, 2 per cent. rather than 5 per cent., I should like his opinion of the treatment by picric acid weaker than the 2 per cent. he refers to. Perhaps he could give his view of the following rather old-fashioned treatment.

Without any preliminary cleansing, gauze packs, wrung out in a solution made up of picric acid 90 grains, industrial spirit 3 oz., distilled water 40 oz., diluted with an equal quantity of warm water, are applied covered with a liberal quantity of wool and bandaged slackly. The dressings are changed easily next day since they will be saturated with dirty

tissue fluids and gross dirt, while considerable coagulation has taken place. The next gauze dressings are left *in situ* and moistened from the outside daily with the same weak picric acid solution till such time as they become non-adherent.

Haydon Bridge, Northumberland, Jan. 11. RICHARD BELL.

Rehabilitation Centres for Injured Workmen

SIR,—I have read with interest the memorandum of the Joint Committee of the British Medical Association and the Trades Union Congress on the subject of rehabilitation centres for injured workmen, a report of which was published in the *Supplement* to your issue of December 18, 1937.

No one can deny the value such centres would be to bridge the gap which at present is inadequately covered by "suitable light work." The organization suggested is admirable and the necessary personnel and accommodation clearly and succinctly set out in a way which reflects great credit on the members of the Committee. Is it wise, however, to jeopardize the realization of such useful centres by serious overstatement of facts? I refer, of course, to the sentence concerning the percentage of permanently disabled men:

"Now that the establishment and reorganization of fracture clinics is developing favourably, it may be anticipated that the proportion in the country as a whole will approximate to that of the fracture clinics already established, where experience has shown that permanent incapacity is inevitable in less than 5 per cent. of industrial injuries. With the continued advances of orthopaedic and traumatic surgery even this figure should be improved upon."

Where are these remarkable fracture clinics to be found? The insurance companies who have a serious financial interest in this do not know them and can produce some surprising figures. One large combine recently asked me if I knew of anything they could do to reduce the period of disability in their insurees and to bring their figures to within even measurable distance of the figures published by the British Medical Association Fracture Committee in 1935. They made the statement that 35 per cent. of men insured under them sustained some permanent incapacity, and that taking each hospital separately this figure did not vary very much whether the hospital had an organized fracture clinic or not. The reason for this similarity in organized and unorganized clinics can easily be explained: the latter tend to transfer their worst cases to the former, improving their own percentage and increasing the percentage of the organized service. But this will not wholly account for the discrepancy between the figures of the British Medical Association Committee and those of the insurance companies. If by permanent incapacity is meant total incapacity, let this be made clear; but I cannot think this is the explanation, for I am sure no hospital, however badly organized, could produce 20 to 30 per cent. total incapacity in the injured admitted to its out-patient department.

I raised such a storm of protest when last I criticized the figures of the B.M.A. Fracture Committee (a criticism which has since been justified) that it is with some hesitation that I enter your columns again. But if, as is suggested, we are to hope for Government support in this excellent system of rehabilitation centres, let us be certain of our facts and figures, in case the Government make further inquiries and discover the overstatement, bringing discredit on the whole scheme and possibly delaying the formation of these centres for some considerable time.—I am, etc.,

Liverpool, Jan. 11.

W. J. EASTWOOD, M.Ch.(Orth.).

When this restriction becomes universal, as it is destined rapidly to do, the competition from the Royal Colleges must automatically disappear, for the exclusively Conjoint student will no longer obtain admission to the medical schools. There can be no doubt that the Royal Colleges have seen the red light of danger from this recent development if Dr. Gray has not. Indeed, it is this threat which explains the present agitated efforts by the Colleges and their supporters to secure an agreement with London University which they hope would avert that exclusion before it becomes actually effective.

Six representatives of the Senate, of whom I am one, sit upon the Court. Had any such consideration as Dr. Gray quite unwarrantably suggests actuated the Court as that an improved entry should be secured by lowering the standard of the final M.B. it would have been the duty of the Senate representatives to protest, and they would not have failed to do so. No such implications can be read into the pronouncement by the Court. The revised regulations for the medical examination of the University, following upon the reform of the curriculum, are designed to make the degree more accessible and would most probably have that result without lowering its standard.

Dr. Gray does not seem to realize that the pious aspiration of the Faculty Board that "the standard of the degree must be firmly maintained" is incompatible with the actual proposition offered by the Board—namely, that the examination in medicine, surgery, and midwifery for the final M.B. (much the most important subjects of the whole curriculum) should in effect be conducted by the Conjoint Board on its present standard. I believe that the great majority of medical educationists would support the unanimous opinion expressed by the Haldane Commission, that the proposed arrangement (essentially the same then as now) would inevitably result in lowering the standard of university education in medicine, where such lowering is least desirable.

The issue raised by the present controversy is of vital importance, for it is to decide which body shall ultimately control medical education in London—the University of London or the Royal Colleges. Largely because of the economic position—namely, the impossibility of carrying out any adequate education of medical students without the aid of grants from the State—the medical schools in London, all of which now accept these grants, are increasingly under the obligation to maintain the university standard in their teaching. London University is alone among universities in being faced with the competition of the "relatively easy (Conjoint) qualification," the existence of which, as Dr. Gray quite properly points out, "affects materially the number who obtain a degree." How that position can be improved by consultation with the Royal Colleges seems difficult to explain. The Colleges cannot be expected to commit *felo de se*.

The rapidly growing importance of the medical profession in the modern State surely calls for the highest possible training of its members, especially university graduates, from whose ranks future teachers are so largely drawn. It would indeed be a disaster if London University, which has so proud a record as a pioneer in raising the standard of its medical examinations when the medical examinations of the other universities were deplorably low, should lead the way now in reducing the standard for its qualifying examination. Happily portents all point to another defeat of this retrograde proposition, so decisively defeated in the past.—I am, etc.,

London, W.1, Jan. 14.

E. GRAHAM-LITTLE.

Who Owns X-Ray Negatives ?

SIR.—The literal reply to this regrettable heading—and at such a season!—is that many people do: for example, all radiologists, most hospitals, some radiographers, a few general and consultant medical practitioners, a number of industrial concerns, and those members of the general public who have purchased the negatives from radiographers, with the addition of hordes of patients who have been given them by their medical advisers.

If, as I suspect was the intention, the question is confined to x-ray negatives taken by or under the instructions of a radiologist, it has been adequately dealt with in the reasoned statement of Dr. Asten and in the United States cases quoted by you. To these, for the benefit of people who insist upon legal pronouncements, may be added at least one in the British Isles—in the case of *de Cadiz v. Dr. O'Hea*, April and June, 1931, when judgment was given for Dr. O'Hea, following the decision of *Boucas v. Cooke* (1903), 2 K.B., 227.

The more serious objection to the heading is that it does not cover the subject-matter, and the correspondence to date shows involvement of the following three questions, of which there is a simple and definite reply to the first only, and that appears to be the least important in the minds of the writers. (A) Who owns a radiologist's x-ray negatives? (B) What should he do with them? (C) What should be their ultimate fate?

(A) In my opinion it would be in the interests of all concerned if the B.M.A. would urge the medical profession to dispose permanently of this question by accepting the view, which is correct both morally and legally, that the negatives are the property of the radiologist, and by educating patients accordingly. It would then be established that a radiologist may retain or call for the return of negatives of a case of particular interest to him or of importance to the furtherance of radiological knowledge, and that he is consulted for the benefit of his experience and special knowledge of radiology, and not as a purveyor of "pictures."

(B) It follows that he should never give them to the patient, and I should be surprised to hear that this is in any way common practice. In my opinion he should give to the referring practitioner a report on his radiological findings, together with any advice which he considers pertinent, and such radiographs as are likely to amplify the report or assist in the diagnosis, prognosis, or treatment of the case. In most cases prints or copies are perfectly adequate for these purposes, and he will not expect them to be returned. If he sends the original negatives and asks for their return they should be returned, but if he does not ask for their return it may be presumed that he is relinquishing ownership. He should be prepared to send the original negatives on request, but not necessarily to allow unrestricted handling of special negatives. If the patient goes to the radiologist without informing his medical adviser the radiologist should stipulate that the name of a medical practitioner be given, with whom he may discuss the case and to whom he will send the report as above.

(C) The ultimate disposal of radiographs of which he has relinquished ownership is not in the province of the radiologist, but I feel that uniformity of procedure in this respect is desirable. The soundest method would appear to be for the patient's medical adviser to retain them with the notes of the case, and to transfer them when necessary to another medical practitioner—for example, if the case or the patient should leave his care—but as many medical practitioners permit or even encourage the

they are expensive, though, as Dr. Jordan says (*Journal*, January 8, p. 96), a correct shoe wears so much better than a "fashionable" one. In "ordinary" shoes one can get a straight inner border for children until they come to size 3. Then (I am thinking of girls) they come under the category of "ladies" and the big toe begins to be deflected outwards. Even canvas "gym" shoes have this fault. One cannot expect the manufacturers to supply a thing for which there is no demand. How does a sense of values change? How did it happen that people began to see "wasp" waists as ugly instead of desirable? How did the Chinese lose their admiration for bound feet? Can we not launch a campaign of articles in the popular press written by orthopaedic experts who could explain the necessity for a "change of heart" about feet? I believe the public look upon hallux valgus, corns, and other preventable troubles as evils that come "out of the blue" and have to be endured. I do not think they have any realization of their cause.—I am, etc.,

London, N.W.1, Jan. 10.

DOROTHY E. MASON.

The Problem of the Final M.B., B.S.Lond.

SIR,—The late Sherlock Holmes was reported (by an M.D.Lond.) to have said of the "agony" column of the *Times* that it amused without fatiguing the intelligence. Had he been spared how he would have enjoyed Dr. A. M. H. Gray's contributions to educational literature!—for instance, Dr. Gray on the economic problems of students (or their parents). Of course, officially speaking, the Board of the Faculty of Medicine has as much to do with the economics of the University and its students as with the economics of rearmament; but Dr. Gray on economics is quite good fun, and we are still near Christmas. Unless either the Colleges or the University will remit their fees (in whole or part) his plan will cost the students more. Of the 399 students who completed the second M.B. in 1926-7 and reached the *Medical Register*, 250 graduated M.B., B.S.; of the 149 who did not 86 never sat for the final M.B. at all, and so saved some fees. Of course if the University waived its fees there would be a saving. But a financially simpler way of reaching the result desired by Dr. Gray would be for the University to take over the whole profitable business of examining. Financially the tacit assumption that the Colleges must have a monopoly of licensing is naive. When the Colleges established their joint board the University of London was what the Colleges still are, only an examining body, and the general educational level of London medical students was so low that but a small proportion even matriculated. Now a large proportion are undergraduates and the University is a teaching as well as examining body. Financially, by entering into direct competition the University could put the Conjoint Board out of business as effectively as the railway companies ruined the stage coach companies, and for much the same reason. The Conjoint diploma is a mere licence to practise; all who take it (save a few stalwarts who protest annually in Lincoln's Inn Fields) recognize it for what it is. A licence granted by the University of London, having the additional advantage of exempting the holder from some part of the final M.B., would be much more attractive. That purely financial argument can only be countered by sentimental or educational arguments.

So we may leave the kindergarten economics of Dr. Gray—with a humble tribute of admiration to his belief that "economic matters are of no interest to the

Universities of Oxford and Cambridge." Indeed, before embarking on economics Dr. Gray should have consulted a senior relative who contributed to your columns some years ago—I will call him Dr. Gray, sen. The occasion was this. At present a large proportion of Cambridge medical students never graduate in medicine (about one-third), but practically all of them are graduates of their university. Sir Ernest Graham-Little wrote to you and suggested that Londoners who had passed the second M.B. might, on fulfilling minor conditions, be admitted to a degree equivalent to that of B.Sc. Professor Lovatt Evans, who knows almost as much about scientific standards as the Gray family, saw no scientific objection, and I (*mea culpa*) urged an economic advantage—namely, those (a small but not quite negligible proportion) who had to give up the medical course altogether might be helped by the possession of a degree. But Dr. Gray, sen., perceived what Professor Lovatt Evans and I had missed—the danger to the prestige of the B.Sc., the possibility, as he put it, that the new degree might come to be thought of as equivalent to Failed M.B., B.S. I am sure that this wise and witty veteran would have reminded young Dr. Gray of the poet who said that presbyter was but priest writ large, and would have warned him of the danger that M.B., B.S. might be thought of as M.R.C.S., L.R.C.P. written in four instead of eight letters. Young Dr. Gray should stick to educational arguments, to which I return.

It is an axiom that, *whenever possible*, the examining and the teaching body should be identical. My italics are the only answer Dr. Gray's boyish attempt to make mischief between "external" and "internal" sides deserves. The University is, in my opinion, competent to control *all* medical undergraduate teaching and examining done in London. If it is a fact that the 40 per cent. of our undergraduates who do not graduate in medicine are, educationally speaking, worthy to do so, it is the duty of the Senate so to rearrange its own examinations that these students do graduate, and to make that rearrangement without reference to the views of financially interested corporations. Dr. Gray and his friends urged the Senate to co-operate with Oxford and Cambridge in an educational inquiry; then they imposed on the teachers and administrative staff of the University the weary business of revising curricula and examinations in accordance with the findings of the joint investigation. Now they tell the Senate and the world that all this will make little or no difference to the proportion of students graduating and that a wholly different plan should be tried. Why was this advice not given three years ago? Is it possible that shrewder politicians than Dr. Gray are afraid that either the reform of the curriculum will be effective or that the absurdity of paying tribute for ever to two corporations will be realized by persons more powerful than any of us medical folk.—I am, etc.,

Loughton, Jan. 16.

MAJOR GREENWOOD.

SIR.—Dr. A. M. H. Gray sees no connexion between my demonstration that the medical schools are increasingly restricting their admission of pupils to university students and my prediction of improvement in the number of students in those schools ultimately taking university degrees. I should have thought the connexion was too obvious to labour. This restriction, initiated by my own school, St. Mary's Hospital, has been in actual operation for less than two years, and yet figures for 1936-7, available only within the last few days, show that two-thirds of the students at London medical schools in that year were reading for a university degree and one-third for non-university qualifications, chiefly Conjoint Board.

of election less cumbersome and more equitable than the present one.

Whatever may have been one's experience, whether as candidate or elector, I think most truthful observers are agreed that there is often no rhyme or reason for what actually happens. It may be urged that a candidate has done no original work; or that he is such a good scientist that his clinical acumen is in doubt. His field of interest may be regarded as too generalized or too specialized. He may be lacking in personality, or have such an attractive one as to threaten other people's popularity. He may suffer, or be favoured, because of belonging to a certain hospital. Prejudice is not limited to the more obvious channels; thus I have heard Welshmen and Scotchmen spoken of disparagingly as such; an Australian was turned down without serious consideration—as if Gallipoli had never been; an English-born sunburnt applicant was excluded because of a suspicion that his melanin was a fat back racial admixture—I subsequently heard that his father was a distinguished Army officer. Some physicians will not support an applicant in their own specialty—others will seek one in order to lighten their own hospital work. A man is often chosen because he will make a good colleague and "be easy to work with"; and yet this proves to be the case no more often than with a more independent-minded person. Many hospital staffs are divided up into cliques. For this very reason an applicant may stand a poor chance because the chief or group he has served does not belong to the "powerful group," or to those who concern themselves more energetically with elections. A candidate may fail to get on his own teaching hospital for one or more of the above reasons, or because there is no vacancy for his particular specialty at the time he is in a position to apply. It may be true that a good man will be stimulated to greater effort and will overcome all difficulties; but many good men will fall by the wayside and will be virtually lost. Others will become embittered and cynically materialistic. They may fail to make their contribution to scientific medicine or surgery because the most creative years of their life have been spent in uncertainty and insecurity, literally wandering from door to door, hospital to hospital; and gradually but insidiously their self-respect and spirit may become undermined.

In another direction Sir Arthur Hurst has recently drawn attention to the appalling lack of co-ordination among the various teaching hospitals in London; and Lord Dawson has also intimated a similar state of affairs in a wider circle. Surely many of the evils of hospital elections could be abolished by a London central election board; or perhaps by groups of hospitals associating together for staff appointments, as do the colleges at Oxford or Cambridge for scholarship purposes. Personal or personality difficulties are usually fantasies that disappear on closer acquaintance, and an interchange of men from different centres could not fail to revitalize and quicken the medical and scientific activity of all hospitals.

—I am, etc.,

London, Jan. 7.

INGENUOUS.

Autophytic Dermatitis

SIR,—Some years ago in China I had as a patient a British schoolgirl, aged 13, who on several mornings had developed oval patches of moist dermatitis about the size of the top joint of her thumb or finger. They were all on the face, and a fresh one appeared each day. I took her into hospital, and after a few days instructed the nurses to keep away all irritants or disinfectants, but the patches

still continued to appear and spread to the arms. They healed in two or three days.

After about two weeks I rubbed a piece of sterile gauze over a fresh patch, then rubbed a piece of healthy skin on her arm with the gauze, and sealed the part with gauze and adhesive plaster to prevent it from being touched. Next morning a similar patch of dermatitis appeared. I told the girl that the previous patches must have been self-inflicted, whether intentionally or in her sleep, and that they must now cease. They did cease, and she went back to school life. She had the reputation of trying to get out of school work.—I am, etc.,

Worthing, Jan. 13

FRED H. JUDD.

Cataract Extraction during Narcosis

SIR,—I am grateful to Mr. Basil Graves for the elucidation of many points raised in my letter. Referring to his remarks (*Journal*, December 25, p. 1303) concerning scopolamine and morphine, I cannot recall any cases of cataract in which their use produced vomiting. As regards psychical disturbance, it occasionally occurs irrespective of any narcotic influence: I am doubtful of its greater frequency after the use of scopolamine and morphine. Of course there is hardly a drug to which some patient or other will not react in an unexpected way.

What stands out from the correspondence is that as an alternative to scopolamine and morphine paraldehyde is a well-tried, efficient narcotic which could be administered either by mouth or per rectum in most cases without fear of any harm arising to the patient therefrom.—I am, etc.,

Eastbourne, Jan. 15.

D. V. GIRI.

Treatment of the Common Cold

SIR,—I was most interested to read Dr. Elyan's experiences in the treatment of the common cold with prontosil (January 15, p. 146). The results he obtains closely resemble those that I am in the habit of obtaining with bicarbonate of soda—one heaped teaspoonful in a half-pint tumbler of hot water, morning, noon, and night for a minimum of twenty-four hours and a maximum of seventy-two. For children, half that quantity.—I am, etc.,

Jan. 16.

SURGEON COMMANDER R.N.

Large Lipoma simulating Goitre

SIR,—I enclose a photograph which if reproduced may be of interest to readers of the *British Medical Journal*. It shows a lipoma of the space of Burns which simulated a pendulous goitre in a single lady 53 years of age. It will be noticed that the resemblance to a goitre was very close. The large rounded lipoma was removed by a curved incision over the upper part of the sternum.—I am, etc.,

Wanganui, New Zealand
Nov. 17, 1937.

H. KENRICK CHRISTIE,
Ch.M., F.R.C.S.

An investigation to determine the relative values of raw and pasteurized milk, produced under typical commercial conditions, has revealed no significant differences in the nutritive value of the two products. The feeding experiments were carried out on calves. The investigation, conducted at the Hannah Dairy Research Institute, Ayrshire, is described in the current issue of the *Journal of Dairy Research*.

patients to demand the radiographs for themselves the inception of such a procedure as routine would present difficulties. I would strongly advise that the patient should not in any case be given possession of the radiographs while treatment of the injury or disease is still being carried out. One reason for this is the difficulty experienced by radiologists in obtaining previous films in "follow-up" cases, and there are other reasons which may affect the patient or the medical adviser, or both.

The above observations are not materially affected by the remarks of Mr. Fairbank (*Journal*, January 8, p. 92), who admits that he is treading on difficult ground, and whose letter applies to an even more restricted type of case than he suggests—namely, that in which the presence of fracture has been established. In the undiagnosed case of suspected injury to a bone or joint the radiologist's opinion may be of supreme importance, and even in the true fracture case his report should be of assistance to the clinician, and therefore of value to the patient. All fracture cases are not sent to surgeons, and all medical practitioners are not sufficiently conversant with radiographic appearances to dispense with advice additional to their personal interpretation thereof.

To those accustomed to them x-ray negatives afford more detailed information than do prints, but I consider that well-prepared and carefully selected and arranged prints, in conjunction with a reasoned radiological report, should be at least as helpful in most cases, and although I do not personally advocate routine prints of fractures they would probably be adequate for "follow-up" purposes. They are infinitely preferable to full-size films from the point of view of transport and storage, and have the added advantage that if they are destroyed or lost they are not irreplaceable, as are the original negatives.

I have indicated above that I sympathize with the medical practitioner who prefers to view the original negatives, and I should always fall in with his wishes in this matter, but the actual ownership of the negatives undoubtedly vests in the radiologist, and I cannot sympathize with the suggestion that in any circumstances the patient should be "entitled to any and all of the films that have been taken."—I am, etc.,

Worthing, Jan. 10.

R. BOULTON MYLES.

SIR.—At the risk of incurring the displeasure of my radiological colleagues, I venture to support some of Mr. Fairbank's contentions (*Journal*, January 8, p. 92).

While I have always held that skiagrams without an expert's report are valueless, I have also always held the converse: that, if the radiologist himself requires skiagrams for the preparing of the report, then this report is useless unless the skiagrams accompany it. I hold therefore that skiagrams should always be furnished, with the report, to the medical man who has requested the x-ray examination.

I also accept the view that the skiagrams are only incidental to preparing an opinion and therefore are the property of the radiologist. He can therefore, if he wishes, insist on their return, but in special cases, such as when the patient is going to a distant part of the country or abroad, he will of course waive this right. In the patient's interest it would be best for the radiologist to keep the skiagrams, because both the doctor and the patient usually lose them and they are not available when a subsequent examination is required. In practice the radiologist will probably find it best not to insist on their return, and then the onus of the subsequent production of the old skiagram will be upon the medical practitioner, or on the patient if they have been given to him. The radiologist

would of course keep a copy of his report indefinitely. I have been asked to produce skiagrams fifteen years after they were taken.

With regard to hospital practice, I always allow a medical practitioner to have the loan of skiagrams, provided they are returned to the hospital, but I make an exception if I think there is an attempt to exploit the hospital for medico-legal purposes.—I am, etc.,

London, W.1, Jan. 15.

N. S. FINZI.

SIR.—Mr. H. A. T. Fairbank, in his letter in the *Journal* of January 8 (p. 92), appears to confuse a difficult and complicated question which in other respects was becoming reasonably clear as a result of the correspondence in your columns. We all know that an orthopaedic surgeon has sufficient knowledge of radiographic interpretation to read skiagrams of simple fracture cases, but I do not know why Mr. Fairbank finds it necessary to write at considerable length in order to point out that in this instance he considers a radiologist to be virtually a "glorified photographer." Every specialist of experience acquires a reasonable knowledge of the work carried out by those of his colleagues with whom he associates, and I am constantly called upon by medical practitioners, particularly in the country, to decide whether or not a bony injury requires the services of a surgeon. I do not think that Mr. Fairbank would be pleased if anyone referred to an orthopaedic surgeon as a "robot who put crooked bones straight." Recently an orthopaedic surgeon for whom I have a profound respect requested me to make my reports on all difficult cases as detailed as possible, remarking that "two brains are better than one," and I fully agree with this observation.

I always provide my colleagues with the evidence on which I base my report, and should a patient change his locality or seek other advice I think that every radiologist would be guided by common sense and courtesy in doing what was required of him. I do not propose to occupy your columns by repeating what has already been said on a number of occasions in a clear and able manner, but I do suggest that we adopt the decision which has been made in the American courts, and which has the support of the majority of radiologists in this country—namely, that x-ray films are the property of the radiologist.—I am, etc.,

Ipswich, Jan. 13.

C. H. C. DALTON.

SIR.—So far as I know, the question of who owns an x-ray film has not yet arisen since the article to which you referred lately in an editorial footnote was written. Dr. W. Asten may, however, be interested in the American decisions enumerated by Dr. S. W. Donaldson in his book *The Roentgenologist in Court*.—I am, etc.,

London, E.C.4.

D. HARCOURT KITCHIN.

* * Dr. Donaldson's book is reviewed on p. 174 of this issue.—ED., *B.M.J.*

Applying for Hospital Posts

SIR.—The recent correspondence on this subject shows that the question of the method of election to hospital appointments, especially of the honorary staff, has only to be mentioned to reveal the numerous hardships the present system entails. Time-wasting and sore feet are the least disputed but possibly the least pernicious defects. It is also obvious that any system might fail to receive more than a minority unqualified approval, since the majority constitute the disappointed ones. Nevertheless it should not be beyond the intelligence and ingenuity of those who might be thought responsible to devise a system

Prussia, aged 84; Professor OTTO KRON, senior physician to the department for cutaneous and sexual disease of the Municipal Hospital, Vienna, aged 61; Dr. MANUEL A. SANTAS, formerly professor of paediatrics at the Buenos Aires Faculty of Medicine; Professor JOSEF LANGE, an eminent paediatrician of the German University of Prague; Professor ARTHUR THOST of Hamburg, a pioneer in otology and laryngology, aged 83; Dr. PAUL ERNST, formerly professor of morbid anatomy at Heidelberg; and Geh. Sanitätsrat Dr. ALFONS STANDER, for many years co-editor of the *Münchener medizinische Wochenschrift*.

EMMET RIXFORD, former president of the American Surgical Association, died in the Peter Bent Brigham Hospital, Boston, on January 2, aged 72. An enthusiastic hiker, one of the peaks of the Sierra range in California is named Mount Rixford in his honour.

Universities and Colleges

UNIVERSITY OF LONDON

A course of lectures and clinical instruction on mental deficiency and allied conditions, arranged by the University Extension and Tutorial Classes Council in co-operation with the Central Association for Mental Welfare, will be given from Monday, March 28, to Saturday, April 9. It will be based on the requirements for the University of London Postgraduate Diploma in Psychological Medicine, and is intended for medical practitioners, more especially those who are engaged as school medical officers, certifying officers to local authorities under the Mental Deficiency Acts, or as medical officers of institutions, or who are otherwise definitely concerned with the care of subnormal or abnormal persons. The course has been re-organized and Part I has been extended to a fortnight in order that considerable time may be given to practice in mental testing under the supervision of a psychologist. Part II of the course, devoted to the problems connected with the retarded and difficult child, formerly held immediately after Part I, will this year be held in the autumn. All lectures will be delivered at the Senate House of the University, W.C., unless otherwise stated on the students' time-tables, and will be given from 10 to 12.30 each morning, with some late afternoon lectures from 5 to 6. The clinical work will be arranged for each afternoon, except Saturday, approximately from 2 to 4 (later in the case of visits to homes and institutions). Detailed time-tables will be sent to each person proposing to attend the course not later than March 21, and forms of application should be filled in and returned by March 7. The University will grant certificates of attendance to those students who attend regularly taking both theoretical and practical work. The registration fee, to be paid at the time of application, is 10s. 6d., and the fee for Part I of the course is £5 15s. 6d. All communications should be addressed to Miss Evelyn Fox, C.B.E., c/o University Extension Department, Senate House, University of London, W.C.1.

Mr. Philip Geoffrey Scott, B.Chir., F.R.C.S., chief assistant in the aural department of St. Bartholomew's Hospital, has been reappointed to the Geoffrey E. Duveen Travelling Studentship in Oto-rhino-laryngology for a further year (1938).

The following candidates have been approved:

M.D.—Branch I (Medicine): J. Apley, C. G. Baker, Jean M. Cass, Lynette Dowsett, E. A. Hardy, G. W. Heam, C. A. Lillcrap, W. N. Mann, S. K. Squires, R. J. Vakil. Branch II (Pathology): D. G. ff. Edward. Branch IV (Midwifery and Diseases of Women): T. L. S. Baynes, P. J. Boyd (University Medal), Anne A. Craig. Branch V (Hygiene): M. Sendak (University Medal).

UNIVERSITY OF MANCHESTER

The Council has approved the appointment of Dr. James Davson as assistant lecturer in pathology.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A quarterly meeting of the Council was held on January 13, with the President, Sir Cuthbert Wallace, Bt., in the chair.

The Hallett Prize, awarded on the result of the Primary Examination for the F.R.C.S., was granted to Bertram Alfred Edward Johns of the University of Birmingham.

It was reported that at the recent Primary F.R.C.S. examination held in New Zealand seven candidates out of fourteen were successful in passing the examination.

Mr. Hugh Lett was appointed the representative of the College on the Council of Queen's Institute of District Nursing. Mr. W. Sampson Handley was appointed Hunterian Orator for 1939; Professor R. E. Kelly, Bradshaw Lecturer for 1938; and Sir Humphry Rolleston, Thomas Vicary Lecturer for 1938. Mr. William Frederick Davis was appointed Assistant Secretary to the College.

Diplomas

A Diploma of Membership was granted to David Allan Richmond of the University of Manchester.

The following diplomas were granted jointly with the Royal College of Physicians:

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—T. J. K. Brownlee, D. F. Buckle, J. P. Child, H. B. Craigie, A. G. Crisp, H. Fishgold, W. H. Fraser, Gertrude M. Jefferson, J. Littlewood, K. O. Milner, J. D. Richardson, P. H. Sandifer, M. Singh, Pauline W. M. C. Stirling, F. H. Taylor, J. C. S. Thomas, J. Walsh.

DIPLOMA IN LARYNGOLOGY AND OTOTOLOGY.—A. S. de B. Coeks, G. S. Dhillon, G. A. M. Knight, H. P. Lawson, G. Phillips.

Diplomas in Anaesthetics were granted, under the special conditions of the Regulations, jointly with the Royal College of Physicians to the following candidates:

W. E. Brown, A. H. Diamond, H. Hunter, Kathleen M. Lyon, Kathleen L. Oldham, E. S. Rowbotham.

The following hospitals were recognized for the six months' surgical practice required of candidates for the final Fellowship: Royal Hospital, Richmond (resident medical officer and senior house-surgeon); St. John's Hospital, Lewisham (resident surgical officer and house-surgeon).

SOCIETY OF APOTHECARIES OF LONDON

The Court of the Society has awarded the Gillson Scholarship in Pathology for 1938 to Dr. R. H. S. Thompson of the Rockefeller Institute Hospital.

The Services

THE ARMY DENTAL CORPS

The War Office invites applications from dental surgeons for appointment to a limited number of commissions in the Army Dental Corps. Candidates will be selected for these commissions without undergoing competitive examination, but will be required to present themselves in London for interview and physical examination. They must be registered under the Dentists Acts or Medical Acts, and be not over the age of 28 years. Successful candidates will, in the first instance, be given short-service commissions for six years, at the end of which period they will retire with a gratuity of £1,000 unless they have been granted permanent commissions. Full particulars and forms of application may be obtained from the Director, Army Dental Service, the War Office, London, S.W.1.

The third International Congress for Microbiology will be held at the Waldorf-Astoria Hotel, New York City, September 2-9, 1939, under the auspices of the International Association of Microbiologists. It will be composed of the following nine sections: general biology, variation and taxonomy; general biology, microbiological chemistry and physiology; viruses and viral diseases; rickettsiae and rickettsial diseases; protozoology and parasitology; fungi and fungous diseases; medical and veterinary bacteriology; agricultural and industrial microbiology; immunology. The general secretary is Dr. M. H. Dawson, College of Physicians and Surgeons, 620, West 168th Street, New York City. The registration fee is \$5.00, which does not include the cost of a banquet ticket or a copy of the *Proceedings*. A World's Fair will be held in New York City during the summer of 1939, and those who wish to attend the Congress for Microbiology should therefore make plans promptly. The American Express Company has been appointed official travel agency. The honorary secretary of the National Committee for Great Britain and Northern Ireland is Dr. R. St. John-Brooks, Lister Institute, Chelsea Bridge Road, London, S.W.1.

Obituary

News comes from Zululand of the sudden death on December 5, 1937, of Dr. DOUGLAS GARNETT STOUTE, district surgeon for Mtunzini and medical officer to the Amatikulu Leper Institute. He had been playing in a local cricket match at Eshowe, and after scoring 66 not out collapsed. The weather was intensely hot, and the game followed a period of strenuous work and long distances of travel. Dr. Stoute was 47 years of age, and graduated M.B., Ch.B. of Edinburgh University in 1916. During the war he served in Salonika, was mentioned in dispatches, and retired with the rank of major, R.A.M.C. He went to Zululand shortly after the war, and soon began to interest himself in social organizations on the Natal coast, particularly sporting bodies. He was chairman and president of various societies, and his practice extended from Mtunzini to Tugela. He leaves a widow and a son.

Dr. ROBERT CROSS, who had practised at Mapplewell, near Barnsley in Yorkshire, for thirty-four years, died on December 27, 1937, not many months after retirement from active work. Born in County Tyrone, Ireland, in 1864, he obtained the L.R.C.S.I. in 1884 and the L.R.C.P. Ed. in 1887. Dr. Cross was well known and much respected throughout the neighbourhood, and especially by the colliery workers of the village, whose "pit doctor" he had been for many years. When any accident occurred at the colliery Dr. Cross was always to be found in attendance on the injured. In September last he received a presentation case of cutlery and an appreciation on vellum from the inhabitants of Mapplewell and Staincross in acknowledgment of his long and faithful service to the community. He had been a member of the Barnsley Division of the British Medical Association for the past thirty years.

Dr. WALTER HOLCROFT CAM, who died last month at the age of 54, was the son of the late Rev. W. H. Cam of Oxford, and from Marlborough went to study medicine at Gonville and Caius College, Cambridge, taking his B.A. with first-class honours in the Natural Sciences Tripos of 1905 after holding an exhibition and a scholarship. At the London Hospital he won the Anderson prize for clinical medicine, and having qualified M.R.C.S., L.R.C.P. in 1909 served as house-surgeon there. He obtained the M.B. and B.Ch. degrees in 1912. During the war he was a battalion medical officer with a temporary commission in the R.A.M.C., and later joined the Royal Flying Corps. In 1921 he began practice at Ross in Herefordshire, and became a member of the honorary medical staff of the Ross and District Hospital. He was also for a time assistant surgeon to the Savernake Hospital, and medical officer of health and inspector of schools for the Marlborough urban district. Dr. Cam was chairman of the Hereford Division of the British Medical Association in 1930-1, and had been president of the Hereford Medical Society. His death from pneumonia is deplored by a large circle of patients and friends who held him in the highest esteem.

By the death of Dr. WILLIAM L. M. GABRIEL on December 30, 1937, the county of Northumberland has lost a loyal and devoted servant and the Territorial Forces a very enthusiastic officer. He was born at Keighley in Yorkshire forty-six years ago, and was a student at Leeds University at the outbreak of the great war. In August, 1914, he accepted a commission in the 2nd West Yorkshire Regiment (P.W.O.) as a combatant officer, and went to France with the 2nd Battalion early in 1915. A few months later he was badly wounded at Aubers Ridge and was returned to England for convalescence. He then completed his medical studies at Leeds University, and

graduated M.B., Ch.B., with second-class honours, in 1917. For a little time he was resident medical officer at the Leeds Public Dispensary, and in 1918 he took a commission in the R.A.M.C. Special Reserve, and for some time was medical officer in charge of the Royal Army Ordnance Department at Chilwell, Notts. From 1923 to 1933 he was medical officer attached to the Tynemouth Heavy Brigade, and he also served with the 149th Field Ambulance Brigade, succeeding to the command of this unit two years ago, representing it at the Coronation last year, when he received the Territorial Decoration for efficiency. In 1920 he was appointed an assistant medical officer under the Northumberland County Council, and remained in its service until his death, acting as medical officer of health for the Gosforth Urban District Council since 1932. In 1933 he obtained the D.P.H. and B.Hy. of Durham University. At the time of his death he had just resigned the last appointment to take over the duties of senior assistant county medical officer of health. "W. F. J. W." writes: Tall and of commanding appearance, with a deep baritone voice and good manners, Gabriel was a charming companion, with what appeared to be a bright future in front of him. He leaves a widow and one small son to mourn his loss. By his own express desire he was cremated, but a memorial service, held in Holy Saviour's Church at Tynemouth on January 3, was crowded, representatives being present from every department of the Northumberland County Council, the Gosforth Urban District Council, Tynemouth Corporation, Newcastle City Council, the British Medical Association, the Society of Medical Officers of Health, and the Reserve Forces Lodge of Freemasons. *Requiescat in pace.*

Dr. ADOLPHUS VAUGHAN BERNAYS, who died on January 8, aged 80, joined the British Medical Association as long ago as 1884, and had practised for many years at Solihull in Warwickshire. His father, the Rev. L. J. Bernays, rector of Stanmore, sent him to Cambridge; he graduated B.A. in 1880, and continued his medical study at St. Thomas's Hospital, taking the M.B. in 1882 and the M.R.C.S. in the following year. He then put up his plate in Solihull, and gradually acquired a large practice, which in more recent times became a partnership of seven. Dr. Bernays was the friend and confidant of generations of patients and took a prominent part in the public life of the neighbourhood. He was a Justice of the Peace, chairman of the Education Committee of the Warwickshire County Council, bailiff of the Governors of King Edward's School, Birmingham, and an alderman of the city of Birmingham.

We regret to announce that Dr. DAVID MALCOLMSON BARCROFT of the Glen, Newry, Co. Down, died on January 13. He was formerly well known as a general practitioner in the west of London, and had been president of the Chelsea Clinical Society. A son of the late Henry Barcroft, D.L., of Newry, he was born in 1875, his elder brother being Sir Joseph Barcroft, F.R.S., lately professor of physiology in the University of Cambridge. David Barcroft studied medicine at the University of Edinburgh, graduating M.B., Ch.B. in 1907 and taking his M.D., with commendation, in 1912. While at Edinburgh he was president of the Royal Medical Society and resident physician at the Royal Hospital for Sick Children. In London he held for some time the appointments of physician to the Margaret Street Hospital for Consumption, and honorary physician to St. Vincent's Cripples Home at Pinner and St. David's Home for Disabled Soldiers and Sailors at Ealing. He was much interested in the treatment of pulmonary tuberculosis, and contributed papers on tuberculin dispensaries and on the administration of tuberculin to the *British Journal of Tuberculosis*.

The following well-known foreign medical men have recently died: Dr. WERNER KÖRTE, for many years surgical director of the Urban Hospital, Berlin, and president of the Central Committee for Postgraduate Instruction in

EPIDEMIOLOGY NOTES

Diphtheria

Diphtheria notifications in England and Wales continue to increase each week; those for the week under review are appreciably greater than those in the corresponding week last year and very much greater than the median value for the last nine years. It is not possible to ascertain what proportion of the cases notified are suffering from clinical diphtheria. When diphtheria is prevalent in an area swabs are taken of the throat and nose in the presence of infections other than diphtheria, and the accidental finding of the organism usually leads to notification as diphtheria, although it may have no relation to the primary disease. During periods of epidemic prevalence of diphtheria the proportion of carriers to cases may be 4 to 1, or even higher, and the presence of carriers in a well-immunized community is common; thereby the specific immunity index of the population is maintained. The discovery of persons harbouring diphtheria organisms among selected groups, such as hospital wards, may have little significance other than that the organism is prevalent in the community. The number of carriers reported may be higher than the actual numbers, as a virulence test for the organism is not invariably applied.

In the last fortnight there were 21 cases of diphtheria, which included six nurses and one ward sister, in the King Edward VII Hospital, Windsor, but no fresh cases were reported after January 13. Three out of five wards were placed temporarily in quarantine, and the children's ward is to remain in quarantine for another week. Five cases of diphtheria have been reported among the domestic staff of the Throat, Nose, and Ear Hospital, Golden Square, London, but patients were not affected. Admission of fresh cases to the wards has been suspended temporarily, but the out-patient department was kept open. A small outbreak affecting four patients was reported last week in the children's ward of the Chesterfield Royal Infirmary. In each instance the measures taken to control the outbreaks appear to have been successful, but the admission of fresh carriers may be expected unless swabs are taken before admission.

Dysentery

The fall in dysentery notifications in England and Wales recorded last week as compared with the previous week has not been maintained. It is possible that the low figures recorded last week were in some measure artificial, due partly to a tendency during the holiday period to postpone notification, and partly to delay in obtaining the reports from outlying districts. The reason to believe that dysentery is still widely prevalent is that because of its mildness it resists the measures usually taken for its control and has acquired the explosive character associated with food poisoning. The outbreak at Bedford last week exemplifies this character well; 70 persons were affected in one day with an attack of Sonne dysentery from a source which has been traced to milk taken from one farm on the outskirts of the town. Pasteurization of the milk supply has been promptly applied and no further cases have been reported.

Although dysentery has only recently been much in the public eye, the present widespread prevalence of the disease, which is not limited to this country but is found also in Germany, Denmark, Norway, Sweden, and Italy, dates from the middle of last year. During the early part of 1937 there was no unusual increase in dysentery in this country. The number of cases notified for the second half of the year shows for the week ending July 3 a total of 35 cases in England and Wales, of which 22 occurred at Walthamstow. For the next two months weekly notifications for England and Wales ranged from 10 to 25. There was a large increase for the week ending September 4 to 154, of which 152 were in Luton: cases

here in the subsequent three weeks caused the returns for the country to be higher than usual. The next outbreak was one of 18 cases in Bilston, Staffordshire, in the week ending October 23. The notifications for England and Wales for the week ending November 6 were 117, this increase being due largely to 43 cases in Farnham, Surrey. Other parts of Surrey were affected in the following week, when 109 cases altogether were notified. London had had on an average less than ten cases each week, but from the middle of September for a few weeks the incidence rose to an average of 20. In the week ending November 20 69 cases were notified. More cases occurred in the following week, and in the week ending December 4 the number of notifications rose to 124. Over 100 cases were notified in each of the next two weeks over a wide area, 25 of the 29 metropolitan boroughs being affected. There was a fall in the week ending December 25, followed by a slight rise in the next week. Concurrently with the rise in the incidence in London in the week ending November 20 there was a rapid rise in the notifications from the rest of the country, when 226 cases were notified. Of the counties, Surrey had the largest number with 43, many of these being at Carshalton. Cases were also notified from Essex, Middlesex, and Kent, from Devon and Dorset, and in some of the large towns such as Birmingham and Sheffield. The 256 cases notified in the country apart from London in the week ending November 27 followed much the same distribution, though Dorset was more heavily affected by reason of 28 cases in Dorchester; during the same period 25 cases were notified from Pewsey, Wiltshire. The incidence of the infection was still greater in these districts in the next week, when a total of 453 cases were notified (of which 124 were in London). The disease appeared in Norfolk, West Sussex, and North Riding for the first time; the Norfolk cases were limited to Norwich and the Yorkshire cases to Easingwold. The week ending December 10 showed the peak of notifications received from the country (excluding London). There had been cases in most of the towns lying to the north of London, the incidence being heaviest in Enfield. Essex in this week continued to receive notifications from Southend, Brentford, and Billericay, while East Sussex recorded 19 cases, of which 13 occurred at Cuckfield. There was a fall in the incidence for the country in the next week, when an interesting contrast was shown in the returns. Devon's 42 cases were scattered throughout 15 districts, while of the 22 in the county of Nottingham 21 were notified from Nottingham itself. There was a further rapid decline in the following week, in which 270 cases were notified, 71 of these occurring in London, while in the last week of the year there were 247 notifications, of which 77 were in London. The notifications of dysentery probably do not provide an exact guide of the true incidence of the disease at all times. After the first case, or perhaps cases, have been proved, whether in an institution or an area, increasing attention is paid to intestinal disorders and a high proportion of cases will be recognized and notified; on the other hand, when the disease remains sporadic many cases are probably completely missed. It is perhaps significant that in non-epidemic times most of the notifications are received from the larger boroughs, such as Newcastle, Liverpool, and London, and it is possible that the heavy incidence in the Home Counties is directly related to notifications from foreign countries. Some importation undoubtedly took place after the war, on the return of troops from Gallipoli, Salonika, Mesopotamia, and Palestine, and even from Flanders. The Flexner organism was the most common strain during the post-war period, but it appears to have been less common in recent years, being replaced by the Sonne variant, which was first identified during the war.

At a recent meeting of the Franco-German Society in Hamburg Professor Mühlens, the director of the Hamburg Institute for Tropical Diseases, presented the Bernhard Nocht medal to Dr. Fournau of the Pasteur Institute of Paris.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended January 8, 1938. Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 125 great towns (i) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns (ii) in Eire. (e) The 10 principal towns (iii) in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

EDITOR OF THE BRITISH MEDICAL JOURNAL. Antiology
Westcent, London.

SECRETARY, *Medisecra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumshugh Gardens, Edinburgh (telegrams: *Asciante, Edinburgh*; telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Hair Dye

"G.P." writes from Ceylon: Will some reader recommend a good and reliable dye for black hair which has gone prematurely grey in a patient aged 30 years, and where it can be obtained.

Incapacitating Diarrhoea

"SRUG" writes: I shall be interested to see the replies to "Emdee's" query (*Journal*, December 11, 1937, p. 1206), as I have been suffering from a similar condition for the past year. In my case, too, all the usual investigations, which have been undertaken in two nursing homes, have failed to indicate any specific cause. Indeed, "rectal ramming," whether undertaken for sigmoidoscopy, x-ray examination, or wash-outs, has always caused greatly increased and prolonged exacerbations of the diarrhoea. In an unsuccessful attempt to keep on in a good whole-time appointment, I have studied colitis to the point of obsession, and it seems to me that the actual cause of this condition is a localized dysfunction of the sympathetic nervous system, resulting in neuromuscular failure with consequent spasticity and atonia. In addition to a history of abdominal symptoms in childhood, perhaps there may also have been some perityphilitis, not necessarily appendicular in type, but possibly tuberculous in origin. Opium in one form or other seems to be the only effective drug, and I have found it best to apply the principle of "little and often" to the diet and to limit drinking to sipping between meals. Charcoal is sometimes useful, a tonic may be tried, and, of course, attention should be given to the balance between rest and exercise and the avoidance of exposure to cold. If a specific causal organism has been found the relevant vaccine may be tried, though even in cases in which none has been discovered anti-dysenteric serum may be effective. There is also bacteriophage therapy, which may be of use.

The Squatting Position in Defaecation

"VIS MEDICATRIX" writes: Everyone who does not adopt the squatting position in defaecation is suffering from partial constipation. Our waste-paper baskets are daily filled with literature on how to cure constipation and avoid its sequelae. John Chiene, late professor of surgery in the University of Edinburgh, and known to thousands of Edinburgh men as "Honest John," gave us a very interesting lecture on his return from the South African campaign on the squatting position. He described how, by carefully weighing his faeces as passed in this position on the veld and as passed in the ordinary pedestal water closet, he found that in ordinary civilian life the rectum was never sufficiently evacuated.

He claimed that the *vis a fronte* suction, or syphonage, moved on the contents of the transverse and ascending colon and prevented the formation of a caecal cesspool. The outstanding advantages of this are too obvious to require stressing. He invented a cataphysical water closet which rather alarmingly precipitated its user into the squatting posture. I think this, and its price of about £5, did not tend to popularize it. Some six or seven years ago I got an advertisement of a simple device that fitted round the base of the pedestal, with jointed foot-rests that folded back out of the way when not in use and could be brought forward into position when required. This cost 10s. 6d. I unfortunately lost this, and have been unable to trace it. Could anyone please advise me where these can be obtained? I feel convinced that if practitioners would adopt the squatting position and ascertain the benefit for themselves, and then instruct their patients accordingly, there would very possibly be much less appendicitis and other pelvic and abdominal troubles and a better level of general health. However small the benefit, it costs nothing, and I am not one of those who believe that because a thing costs nothing it is worth nothing. A further use of this position is during labour: the gains are obvious—for example, gravity acts directly, extra powers of expulsion from pressure of thighs on abdomen, shortening of the third stage, etc. In these days of ante-natal work it is easy to train patients.

* * We cannot trace the device mentioned by our correspondent; but J. A. Hornibrook in *The Culture of the Abdomen* describes and figures an appliance marketed by Messrs. Doulton and known as the "health closet," with a low seat higher in front than at the back.

The Development of Obstetrics

Dr. JOHN LOGAN (Lincoln) writes: On lately reading Playfair's *Midwifery*, printed in 1886, I was impressed by the stress laid on the operations of craniotomy, cephalotripsy, etc., practised in cases of gross disproportion. From the numbers quoted such operations appear to have been far more frequent then than is the case to-day; no mention is made of trial labours. Are the pelvis of the women of this century broader, and the musculature better developed, or is there less interference with Nature and better diagnosis? Caesarean section is described as a desperate last hope, only to be resorted to when even a mutilated foetus cannot be extracted. Commonly it was attempted from two to six days after the onset of labour, following the failure of attempted cephalotripsy, and with the patient moribund. Since transfusion at that time was commonly by the arm-to-arm method, irrespective of blood grouping, or perhaps after a preliminary defibrination of the donor's blood by whipping with a twig, and since even the injection of whole sheep's blood was undertaken, we can well realize the hopelessness of the Caesarean operation. I would like to hear an authoritative pronouncement, telling in detail the indications for these two distinct attacks upon the foetus *in utero*, and indicating whether the approach per vaginam is still used or whether it has been discarded mainly in favour of abdominal section. In my experience even the application of forceps (never by chance allowed me when putting in my number of cases as an intern in a lying-in hospital) is fast becoming a mysterious art, almost beyond my capabilities, to be attempted only when conservative treatment has failed. When *laissez-faire* has brought those obstinate cases of inertia of the uterus and bony disproportion to a standstill, a speedy removal to a maternity hospital or nursing home and the care of a specialist in the art disposes of the resulting embarrassing situation.

LETTERS, NOTES, ETC.

Angiospasm and Head Injuries

Dr. N. PINES (London, E.1), in connexion with the papers by Professor E. Mapoither and Dr. J. P. Martin published in the *Journal* of November 27, 1937 (pp. 1055 and 1051), writes: In many cases of so-called traumatic neurosis a proper examination of the vascular system will reveal a state of angiospasm in different parts of the body, affecting sometimes the cerebral blood pressure, as measured by the method of Baillart: the method is difficult, but once mastered is invaluable and certain. It is a great pity that in this country the study of angiospasm is not pursued actively.

VITAL STATISTICS, ENGLAND AND WALES, 1937

We are indebted to the Registrar-General for the following statement regarding the provisional birth rates and death rates, and the rates of infantile mortality, in England and Wales and in certain parts of the country during 1937. The statement is issued for the information of medical officers of health.

ENGLAND AND WALES

Birth Rate, Death Rate, and Infant Mortality for the Year 1937
(Provisional Figures)

	Rate per 1,000 Resident Population		Deaths under 1 year per 1,000 Registered Live Births
	Live Births	Deaths (Crude Rates)	
England and Wales	14.9	12.4	58
125 county boroughs and great towns, including London ..	14.9	12.5	62
148 smaller towns with estimated resident populations of from 25,000 to 50,000 at the 1931 Census	15.3	11.9	55
London (administrative county)	13.3	12.3	60

Note.—The birth and death rates for England and Wales as a whole are calculated on the estimated mid-1937 population, but those for the towns' aggregates and for London are calculated on the estimated mid-1936 populations.

The birth rate for 1937 is 0.1 above that for 1936, 0.2 above that for 1935, and 0.5 above that for 1933, the lowest recorded.

The crude death rate is the highest recorded since 1929, and is 0.3 above that for 1936, an increase which is largely associated with the heavy influenza mortality of the first quarter of the year.

The infant mortality is 1 below that of 1936, and only 1 above that of 1935, the lowest recorded.

Medical News

The Wandsworth Division of the British Medical Association and the London Panel Committee have arranged a meeting, to which all insurance medical practitioners in the London area are invited, to be held at Wandsworth Town Hall on Tuesday, February 1, at 9 p.m., when Dr. H. Guy Dain will give an address on "How Far has National Health Insurance Practice become More Exacting?"

The Marylebone Division of the British Medical Association has arranged a meeting, to be held at the Medical Society of London, 11, Chandos Street, W., on Wednesday, January 26, at 8.30 p.m., when Dr. Charles Hill, Deputy Secretary of the Association, will open a discussion on "The Osteopath and State Registration," and will be followed by Sir Robert Stanton Woods, Dr. C. B. Heald, Dr. Kelman Macdonald, and Dr. N. J. Macdonald. All interested are invited to attend.

A business meeting of the Association of Industrial Medical Officers will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Friday, January 28, at 5 p.m. At 6 p.m. Dr. S. W. Fisher, H.M. Medical Inspector of Mines, will speak on "The Health of the Coal Miner." The discussion will be opened by Dr. A. J. Amor. A demonstration of radiology and pneumoconiosis will be given by Drs. S. W. Fisher, A. J. Amor, E. R. A. Merewether, C. L. Sutherland, and A. Meiklejohn. The dinner of the association will be held at 8 p.m. On Saturday, January 29, at 10 a.m., there will be a visit to the Home Office Industrial Museum, Horseferry Road, S.W.

A meeting of the Medical Section of the British Psychological Society will be held at the Pharmaceutical Society of Great Britain, 17, Bloomsbury Square, W.C., on Wednesday, January 26, at 8.30 p.m., when a paper will be delivered by Professor J. E. Marcault on "Relationship of Consciousness and the Functional Activities of the Organism."

A meeting of the Medico-Legal Society will be held at 26, Portland Place, W., on Thursday, January 27, at 8.30 p.m., when a paper will be read by Major D. P. Lambert, I.M.S., on "Some Aspects of Medico-Legal Work in India."

The Association of Clinical Pathologists has arranged a scientific meeting, to be held in London at St. George's Hospital on Saturday, January 29, at 9.30 a.m. The annual general meeting of the Association will be held after the tea interval.

A quarterly court of the directors of the Society for Relief of Widows and Orphans of Medical Men was held on January 5, with Mr. V. Warren Low, president, in the chair. Two new members were elected and the death of one was reported. A sum of £2,183 15s. 5d. was voted for the payment of the half-yearly grants to the sixty-one widows and five orphans in receipt of relief. Three special grants of 50 guineas per annum were made to three orphans who had reached the age of 16, when ordinary grants cease, to enable them to continue their education. A first application for relief was received from the widow of a deceased member, and she was voted £50 per annum from the ordinary funds and £25 per annum from the Brickwell Fund. A further legacy of £167 16s. 3d. has been received from the executors of the late George Cattlin, bringing the total amount received from this source up to £4,242 19s. 7d. As the society celebrates the 150th anniversary of its foundation this year it was decided to hold a dinner on October 29, to which all members should be invited, together with distinguished guests. The details of the function will be further discussed at the April meeting of the court. A cordial vote of thanks was passed to Dr. Morland, who, owing to increased pressure of work, has resigned the chairmanship of the propaganda subcommittee. Dr. Morland has done strenuous work in endeavouring to obtain new members. He pointed out that at least twelve new members should be elected every year to keep the membership at its present total. Membership of the society is open to any registered medical man who, at the time of his election, is residing within a twenty-mile radius of Charing Cross. Relief is only granted to widows and orphans of deceased members. Full particulars may be obtained from the secretary of the society, 11, Chandos Street, Cavendish Square, London, W.1.

The *Archives de Médecine des Enfants*, edited by the veteran paediatrist, Dr. Jules Comby, assisted by his daughter, Dr. Marie-Thérèse Comby, has just completed its fortieth year of publication. An interesting history of its career is given by the editor in the January issue.

The Press Association was informed at the offices of Mr. E. R. Kisch, a London solicitor, on January 13, that he had issued a writ that day on behalf of a Croydon resident, claiming damages from the Croydon Corporation. The claimant alleges negligence and breach of statutory duty in connexion with the typhoid epidemic.

Between 1903 and 1916 the American Medical Association regularly published summaries of the fireworks injuries sustained on each Fourth of July, which is a legal holiday in every State of the United States. In 1916—the first year without a single case of tetanus—these reports were discontinued for twenty-one years. Last year the *Journal of the American Medical Association* (November 27, 1937) again took up the story with a summary of the 1937 Fourth of July casualties, reporting twenty deaths and two cases of tetanus which recovered. The total number of injuries was 7,205, a figure which admittedly errs on the side of underestimation. Some of the eye injuries were appalling, and many children will bear their scars for the rest of their lives.

The British Red Cross Clinic for Rheumatism has benefited to the amount of £1,113 14s. 5d. from the Red Cross Ball held at Grosvenor House on November 24, 1937.

Sir Samuel Brighouse, who is now aged 88, has just completed fifty-four years as coroner for South-West Lancashire, during which time he has held 25,000 inquests.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

62

Anterior Poliomyelitis

H. WILLI (*Schweiz. med. Wschr.*, December 25, 1937, p. 1227) describes an epidemic of infantile paralysis in Zürich in 1936. During that year cases in the whole of Switzerland numbered 1,269—an incidence of 3.15 per 10,000 inhabitants, as compared with the previous maximum of 0.87 (1931). The common seasonal peak in August and September was shown, but the curve of incidence showed no relation to variations in the atmospheric temperature. Other common epidemiological findings here confirmed were: (1) radial extension from thickly populated epidemic centres; (2) different distribution in the country and in towns—in the former a greater absolute and relative frequency, in the latter repeated relatively small epidemics; (3) a much greater frequency in the country of multiple infections in one family. The town of Zürich, with 300,000 inhabitants, had 2.6 cases per 10,000 inhabitants; small country towns (2,000 to 8,000 inhabitants) had as many as 18 to 117 cases per 10,000 inhabitants. The total Swiss mortality was 9 per cent.; in one canton 42 per cent. of adults attacked died. In small and relatively isolated communities it was common for widespread, apparently influenzal attacks of illness to appear, followed by a few cases with paralytic symptoms. Abortive cases were much more frequent than paralytic cases. Striking and unexplained inequalities of incidence were seen in adjoining and similar districts in Zürich. From an analysis of cases in small communities it seemed clear that infection was chiefly conveyed either by healthy carriers or by those who had had the disease in an abortive form unattended with paralysis. Willi believes that in prophylaxis the use of serum from convalescents is of more value than adult serum; he found both useless in the paralytic stage, and often disappointing in that preceding it. An effective tested serum is not available in Switzerland; among the difficulties is the fact that not every convalescent serum is protective—its degree of efficacy must be established by tests in monkeys. The value of active immunization by an attenuated virus, as recently tried in America, has yet to be proved.

63 J. HASS (*Wien. klin. Wschr.*, December 10, 1937, p. 1670) draws attention to the fact that despite serum therapy in anterior poliomyelitis greater or less paralyses must be reckoned with in 50 per cent. of cases. Prevention of the contractures due to disturbance of normal muscular antagonism is of primary importance. When contractures are present they may in some cases be overcome by a series of small pulling movements which do not give rise to pain. Strengthening of the musculature is produced by baths, massage, electricity, and gymnastics. Warm spring therapy—that is, swimming and gymnastic exercises in warm water—has been advocated in America. Hass urges the necessity for getting patients on their feet again. He points out that even when complete paralysis is present suitable apparatus can make walking possible. By these means muscle and joint atrophy is prevented. Of operative measures tendon transplantation has given the most brilliant results. Arthrodesis after the age of 18 is of benefit to certain patients. The indications for this operation require to be gone into very thoroughly. The author believes that the treatment of paralyses following anterior poliomyelitis should be carried out in special hospitals equipped with special apparatus, for treatment, however costly, involves less expense than complete crippling.

64 Cerebrospinal Fever in the United States

S. E. BRANHAM (*Bull. Off. int. Hyg. publ.*, October, 1937, p. 2148) states that the years 1930 to 1935 may be regarded as an endemic period of cerebrospinal fever in

the United States. The number of cases fell to a low level, and the mortality in several hospitals was only 20 per cent. At that time there was a certain increase in the relative incidence of Type II meningococcus. In 1935 the disease resumed epidemic proportions, and in 1936 the notifications were higher than they had been at any time since 1930, the highest incidence being east of the Mississippi. The gravity of the outbreaks varied considerably, the mortality being only 20 per cent. in some places and 50 per cent. or more in others. Moreover, while in some localities complications such as deafness and blindness were frequent, in others they were completely absent. In the epidemics of 1928 to 1930 meningococci of Types I and III predominated; about 90 per cent. of the strains found during the period 1930–5 are of the same types.

65

Prognosis in Syphilis

G. WILLNERS (*Nord. med. Tidskr.*, October 30, 1937, p. 1784) has investigated the after-histories of the patients treated for recent syphilis with mercury at the St. Göran Hospital in Stockholm in 1913. Of the 364 patients 270 were males whose average age was between 27 and 28. The follow-up investigations concerned the male patients, eighty-three of whom could not be traced. The state of health of the 140 still alive was not ascertained, but among the forty-seven who had died there were five whose deaths were due to such diseases as aortitis, dementia paralytica, and cerebral thrombosis. There were eighteen patients the possible connexion of whose deaths with syphilis could not be verified. It could not, for example, be established whether the four cases of drowning and one case of death by hanging in this group of eighteen had or had not any connexion with the syphilis of 1913. In the remaining twenty-four cases death was notified as being due to such non-syphilitic diseases as tuberculosis (ten cases), pneumonia, influenza, cancer, etc. The author concludes that there should have been only thirty-two deaths instead of the forty-seven actually recorded if the expectation of life for men in Stockholm between 1921 and 1930 be taken as a standard for comparison. The life insurance societies are therefore justified in regarding the expectation of life in male syphilitics whose first infection dates as far back as 1913 as subnormal.

Surgery

66

Sarcoma of the Breast

S. SAILER (*Amer. J. Cancer*, October, 1937, p. 183) points out that as primary sarcoma of the breast is a rare condition the prognosis following surgical treatment and the biological reaction of these tumours to radium and x rays are still imperfectly known. Malignant connective-tissue tumours of the breast may arise in pre-existing fibroadenoma or may spring from any part of the pectoralis major fascia, the trabeculations of which constitute the supporting septal framework of the breast. The fat, nerve, and underlying muscle may also give rise to sarcomatous neoplasms. Mammary sarcomata constitute only about 1 per cent. of malignant breast lesions. Fifteen cases of primary sarcoma of the breast are analysed and described. Twelve of these are simple, being derived from a single type of connective tissue: three were of the mixed type. Five cases were of the spindle-celled type of fibrosarcoma; two of these arose in fibroadenoma with slow growth until malignant change took place. Of these five patients one is known to be alive and well ten years after the removal of the tumour. Two tumours classified as fibromyxosarcomata showed marked differences in the amount of myxomatous tissue. There were three examples of polymorphous fibrosarcomata which appeared to be rapidly infiltrating tumours. One

The Cause of Acute Rheumatism

Dr. G. ARBOUR STEPHENS (Swansea) writes: Professor McNee is reported on p. 1089 of the *Journal* of November 27, 1937, to have said that none of the hypotheses of the cause of acute rheumatism—streptococci, allergy, or filterable virus—was at all convincing. May I be allowed to draw attention to the last medical report to the Colonial Office in the Falkland Islands, in which, it is stated, there is permanently damp weather with little sunshine, the houses are damp, the soil acid, the food so poor that the school children wear dentures, and septic tonsils full of streptococci are very prevalent. Whilst all the conditions necessary for the streptococci to act are present, yet there are no cases of acute rheumatism. Does not this dispose of the streptococcal theory? My belief is that acute rheumatism occurs in children of the "acid class" (whose pH is increased), the determining factor being a protozoon carried by an insect such as harvest bug, midge, or flea. On the Islands it is obvious the children are of the "acid class," but there are no insects, no fleas, bugs, or midges to bite these children, and so no protozoal parasite is carried.

The Care of the Hypodermic Syringe

No one will deny that the hypodermic syringe is one of the most important weapons in the doctor's armamentarium. Some may even think that its use is so thoroughly understood that it is a work of supererogation to discuss it. There are, however, a few points in its management which will bear emphasizing, even to a generation which is so familiar with its employment. It would be superfluous to labour the need for absolute asepsis, a lesson of the medical student's cradle. That this lesson has been thoroughly learned is proved by the rarity of sepsis as a result of hypodermic medication. The next point is the advisability of causing the minimum of pain. Patients do not like being hurt, and here two considerations must be borne in mind. The needle must be the finest possible and irreproachably sharp. It is not very difficult to keep a needle sharp provided that care is taken not to boil it for long periods. Needles must be boiled, but they should only be immersed for a few seconds at a time. In these days it is more expensive to have needles resharpened than to buy new ones, which luckily are quite cheap, and if there is an extravagance which is pardonable on the part of a doctor it is in keeping himself well supplied with hypodermic needles of blameless acuity. Oily and viscous solutions, which are not readily drawn up into a narrow tube, often have to be injected through a needle of fine bore. But when such a solution is once introduced into the barrel of the syringe it can be forced out through a comparatively fine needle if sufficient finger pressure is supplied to the piston. For this reason it is often advisable for filling purposes to detach the needle, dip into the oily solution the glass nozzle, and draw the oil straight up into the barrel; after which the needle can be replaced and the desired dose administered through it. But care must be taken in doing this to hold the base of the needle with the finger and thumb firmly against the glass nozzle so that the firm pressure needed to force the oil through the narrow metal tube does not cause it to part company with the barrel, thus wasting the contents. From time to time one hears of cases where the needle breaks off and the distal portion becomes buried under the patient's skin. This accident, which has been known to lead to legal proceedings, is not really difficult to avoid. Fracture of the needle always takes place at its junction to the base. This is where corrosion is liable to set in, and is another argument for never using the same needle too long and too often; but in any case the danger of burying the needle in the patient can always be avoided by taking care not to plunge it in right up to the hilt. Provided this precaution is taken, even if the needle should break there will be a projecting portion, which can easily be grasped and drawn out. As regards the care of the glass barrel of the hypodermic syringe, the chief risk to its integrity occurs during the frequent boilings to which it must be subjected. The risk becomes much increased in the case of large syringes such as are used more and more nowadays for intravenous injections. Heat-resisting glass has been introduced for this reason, but syringes constructed of this material are much more expensive than others, and the life of ordinary glass barrels is much prolonged if care be taken to keep them from resting on the bottom of the sterilizer. Everyone knows that the barrel should never be boiled with the piston *in situ*, and it is a good plan to

support the barrel, and the piston also if made of glass, in the metal frame invariably supplied by the makers for holding them in their case. This ensures that the whole barrel is heated evenly and does not bump on the bottom of the sterilizer. It need hardly be said that the barrel of the syringe should be carefully cleaned every time it is used, but this is not always quite easy. Some of the solutions and emulsions for which it may be employed are liable to leave adherent deposits behind them. A great deal can be done with a pledget of cotton-wool grasped in a pair of fine forceps, but even this is not always adequate to remove the last traces of a mercurial or bismuth cream. In such cases an effectual cleansing may usually be obtained by passing either benzine or petrol through the syringe, afterwards removing all traces of it with methylated spirit.

Infection from Fresh-water Molluscs

Dr. F. GORDON CAWSTON writes from Durban, South Africa: The occasional reports of human infestation with trematodes and the regretted death of a conchologist from carcinoma of the liver suggests that more use be made of the eosinophil count in persons who handle fresh-water molluscs, and are thus liable to attacks of free-swimming cercariae. Ignorant persons, and especially natives, should not be encouraged to handle these molluscan hosts, and, where an obscure disease of the liver occurs in a collector, early attention to the presence of infection may save a parasitic condition from becoming malignant.

Osler in 1877-8

Dr. A. D. WEBSTER (Edinburgh) writes: The note on "Osler's First Appearance in Print" in the *Journal* of November 20, 1937 (p. 1026), prompts me to send the following reminiscence. Osler was professor of physiology in McGill University, Montreal. His habit was to invite the class to come at 8 p.m. to the General Hospital mortuary to follow up any particular case in his wards that had died. He was at that time particularly interested in pernicious anaemia, and of cases of these he examined every organ of every system. The very old basement room is fixed on my memory. He would work to the end and we would preserve the parts of the various tissues that he would examine later. How he toiled hour after hour—all of us nearly frozen; sometimes the hours went on beyond twelve before he would be satisfied. I see him now, his hands in the body and asking one of us to use his handkerchief for him, he hardly raising his head from his work. Such was dear Osler in those early days of his career.

Convalescent Homes for the Poor

A short sixpenny history of the Metropolitan Convalescent Institution (14, Victoria Street, S.W.1) has been compiled by an anonymous authoress. The Institution was founded nearly a hundred years ago by Theodore Monro, a promising young St. Bartholomew's physician, who died at the age of 24. He was making his round at the hospital when he was touched by the distress of a woman who was about to be discharged to her slum dwelling, with no means of getting the country air which the doctors said was necessary to complete her recovery. Thereupon he summoned a meeting in Wigmore Street, and the movement was started for providing homes wherein convalescent care for the Institution has well-equipped and pleasant homes at Walton-on-Thames, Bexhill, Broadstairs, and elsewhere, and since its foundation 400,000 men, women, and children have enjoyed the benefit of such provision. The story of this modest, unpretentious work was well worth recording.

Disclaimer

Dr. MICHAEL ELYAN writes: The use of my name in the public press in connexion with a letter published in last week's *British Medical Journal* was without my consent.

Corrigenda

A strange blunder crept into an annotation on Robin and John Adair on December 25 last. In speaking of General Wolfe we referred to his death "on the Plains of Abraham outside Montreal." As all the world should know, the Plains of Abraham lie close to the city of Quebec. Our notice of Dr. John Rickman's *General Selection from the Works of Sigmund Freud* (January 15, p. 125) gave the name of the publishers incorrectly. The book is published by the Institute of Psycho-Analysis and the Hogarth Press.

Anaesthesia

72

Anaesthesia in Cerebral Surgery

G. KAYE (*Austral. New Zeal. J. Surg.*, October, 1937, p. 134) discusses at length the problem of anaesthesia in cerebral surgery, and emphasizes the importance of team work. His conclusions are based on seventy-seven operations on sixty-three patients, in which most varieties of anaesthesia were used. Chloroform only appears twice, as a supplement to local anaesthesia, being found too depressing for general use. Gas and oxygen by endotracheal inhalation (Magill) is favoured, and has latterly tended even to replace local anaesthesia, which may be unacceptable in the lengthy modern operations, and which is undesirable for children. Should general anaesthesia be required at all it is best given from the first, since induction during operation may lead to difficulties. The endotracheal route ensures a free airway at all times, and allows adequate artificial respiration in the event of serious collapse. Any tendency to anoxaemia is dangerous and leads to shock; therefore the oxygen percentage must be kept as high as possible throughout. The anaesthetist should carry out a complete preliminary examination, assess the risk, and order the premedication. The latter presents difficulties, due to the uncertainty of response and the need for avoiding undue depression. Generally, before local anaesthesia morphine grain 1/6 to 1/4 proved most satisfactory, with hyoscine grain 1/200 to 1/150. Before giving gas and oxygen, morphine grain 1/6 to 1/4 was used, with 1½ grains of nembutal orally in nervous persons. During operation shock should be avoided as far as possible by maintaining warmth, careful haemostasis, a free airway, and an adequate oxygen supply. Close observation for the early detection of shock, as indicated by a systolic blood pressure of less than 80 mm. Hg or a diastolic pressure of less than 60 mm. Hg for longer than twenty minutes, is ensured by recording and charting the pulse and respiration rates, systolic and diastolic pressures, and general condition every five minutes. The behaviour of the pulse rate cannot be relied on in estimating shock, as in general surgery, for in the presence of a falling blood pressure it may rise, fall, or remain unaltered. Shock is most commonly due to haemorrhage, and its treatment is suspension of the operation, if possible, pending transfusion with saline, or blood when available, up to one pint. Drugs were generally of little value, though pituitrin and coramine were occasionally useful in emergencies. A remarkable feature of this form of surgery is the way in which the most profound degrees of collapse may be tided over by early and adequate treatment and the operation successfully terminated.

73

Local and Intravenous Anaesthesia

P. FELDWEIG (*Schmerz Narkose-anaesth.*, October, 1937, p. 104) claims that the adoption of local anaesthesia has materially diminished post-operative mortality and morbidity in the Pforzheim Women's Hospital, where previously anaesthesia by means of punction followed by ether had been the routine. Many operations, notably Caesarean sections, can be carried out with local infiltration alone; where further anaesthesia is required small amounts of evipan or eunarcon are given intravenously. The author shows that in one and a half years of administering ether anaesthesia the total operative mortality was 2.4 per cent., and in two and a half years in which local anaesthesia was the routine only 0.8 per cent. Considering laparotomies alone, during these periods the mortality of 192 cases anaesthetized with ether was 5.5 per cent.; of 198 under local anaesthesia (139 Caesarean sections), nil; and of 271 under local with intravenous anaesthesia 2.2 per cent. He claims that the most valuable prophylactic against thrombosis and embolism is immediate standing and walking after operation, and holds that

the longer or more severe the operation and the worse the patient's condition the more important is it that she should walk at least a few steps immediately afterwards. The doses of evipan, etc., are therefore kept as small as possible. Of about 400 patients who underwent laparotomies and were kept in bed, four died of embolus, but there were no deaths from this cause among the last 250, who were made to walk at once.

74

Closed Circuit Gas-Oxygen Anaesthesia

J. DEMIRLEAU and T. COSTET (*Anaesth. et Analgés.*, November, 1937, p. 442) report enthusiastically upon nitrous oxide and oxygen given in closed circuit with carbon dioxide absorption, after an experience of 164 cases of diverse character. They use a Foregger machine, and in 20 per cent. of cases intubate the larynx, the endotracheal tube having an inflatable cuff to exclude air. Ninety-six cases without intubation needed on an average 4½ drachms of ether: twenty-seven with intubation required an average of 9½ drachms. Soneryl by mouth and morphine and scopolamine are given as premedication, while very nervous patients are induced in bed with evipan. During operation the pulse, blood pressure, respiration, and general condition are observed and charted every five minutes. The advantages of the method are the pleasant induction and recovery, with few after-effects; smooth anaesthesia with quiet breathing; conservation of warmth and water vapour; absence of shock; and, with intubation, safe control of the airway. The method is also economical. The authors enumerate and refute the various objections which have been brought against gas-oxygen anaesthesia.

75

Spinal and Intravenous Anaesthesia

R. JARMAN (*Brit. J. Anaesth.*, October, 1937, p. 20) considers that all patients should be rendered unconscious before spinal anaesthesia, for their comfort and for the prevention of psychic shock, and should be kept so throughout the operation. The technique he recommends is as follows: (1) omnopon grain 1, 3 with scopolamine grain 1/150 is given one hour before operation; (2) pentothal sodium 10 c.cm. of a 5 per cent. solution is administered intravenously while the patient is still in bed; (3) 10 to 14 c.cm. of a 1 in 1,500 solution of percaine at body heat is injected intrathecally in the second or third lumbar space, with the patient in the sitting position (Etherington Wilson). The actual injection should take twenty seconds, and the level of anaesthesia depends on the length of time the patient is subsequently kept upright: twenty-five seconds gives anaesthesia to the level of the pubes, thirty-five to the umbilicus, and forty-five to the epigastrium. For chest operations eighty seconds or even more may be needed. After the correct time has elapsed the patient is placed flat, the table tilted 15 degrees, and the operation may be begun. The author claims an entire absence of post-operative headache or backache with this method.

76

Analgesia and Anaesthesia in Obstetrics

W. BOURNE (*N.Y. St. J. Med.*, November 15, 1937, p. 1905) discusses analgesia in labour and briefly reviews the methods in use. In the early stages he favours pentothal orally, as it is free from toxic effects, shortens the duration of labour, and does not cause restlessness or excitability. A dose of 4 grains, to which may be added 1/150 to 1/100 grain of hyoscine, is given at the onset of labour, followed by 2 or 3 grains of pentothal every half to one hour as required. Later he favours intermittent gas and oxygen, if skilled assistance is available, but he condemns all methods of self-administration and warns against the dangers of anoxaemia. Cyclopropane is preferable to nitrous oxide on account of the abundant oxygen available, and is always desirable in the terminal

patient died from lung metastases six months after the removal of a small tumour. There was one case of a neurogenic sarcoma and one of a rhabdomyosarcoma; in the latter case the course was rapid, metastases developing in the lungs, intestine, liver, and lymph nodes. Of the three patients with complex tumours one with a chondromyxofibrosarcoma died within six months of a biopsy of the breast, but another with an osteochondrofibrosarcoma is alive and well two years after a simple mastectomy. In a third case, diagnosed as carcinosarcoma, death occurred five days after operation from cardiac failure. It is seen that these sarcomata are in general very malignant, but the degree of malignancy varies greatly with the type of tumour.

67 Operative Treatment of Fractured Patella

K. MEISSNER (*Zbl. Chir.*, November 20, 1937, p. 2685) states that from 1926 to 1935 ninety-one fresh cases of fractured patella were treated in Böhler's clinic in Vienna. He believes that all cases of fractured patella with separation of the fragments require operation. Conservative treatment is reserved for those without separation, for its application in cases showing some degree of separation is always attended by some loss of function. Meissner was able to follow up thirty-one cases on which operation was performed. All ages from 10 to 80 years were represented. He is of the opinion that operation may and should be performed at any age provided that the patient is in good condition. He describes in detail the case of a man of 77 with separation of the fractured fragments of the patella in which operation was completely successful.

68 Gangrene of the Scrotum

A. E. GOLDSTEIN and B. M. JAFFE (*Urol. cutan. Rev.*, November, 1937, p. 779), who record two personal cases and review the literature, state that this uncommon condition was first described by Boerhave in 1753, in a man aged 40, following retention of urine. Its cardinal features are: (1) sudden onset in apparent health; (2) rapid development of the mortification; (3) apparently total absence of any of the usual causes of gangrene. Gangrene of the scrotum and penis occurs with no particular predilection for any age. The authors' two cases occurred in men aged 56 and 63. The first patient died suddenly a week after excision of the right testicle and part of the cord, and the second patient, a diabetic, made a complete recovery after excision of the gangrenous tissue.

69 Danger of Urethral Instillations of Oil

T. KATZ-GALATZI (*J. Urol. méd.-chir.*, October, 1937, p. 300) points out the danger which may result from the practice of injecting oil under pressure into the urethra in cases of stricture or other conditions. There is always a possibility that the oil may pass into the general circulation and form an oil embolus, with fatal results. In modern urethrography iodopine or lipiodol is the oily substance most commonly used. It is urged that the introduction of these substances into the urethra has been known to cause a fatal embolus during such an examination, and several instances are quoted in which the opaque fluid has penetrated into the veins. The essentials demanded of a fluid to be used for urethrography are that it shall be sufficiently opaque, non-toxic, non-irritant, of a stable composition, and that it may be easily sterilized. It has been found as the result of a study of some hundreds of cases that solutions of uroselectan (30 per cent.) and of thorotrast have proved most satisfactory as regards opacity and are not accompanied by the dangers which attend the use of lipiodol or other oily substances. Three cases are fully described in which urethrography was carried out, and although the liquid was seen to penetrate into the veins there were no ill effects of any kind.

Therapeutics

70 High Altitude Treatment of Asthma

U. CARLBORG (*Hygiea*, Stockh., August 31, 1937, p. 600) has undertaken a study of the 518 asthmatics who, in the period 1923 to 1933 were given institutional treatment at about 450 metres above sea-level, under the Swedish national health insurance scheme. To qualify for high altitude treatment the patients had to be considered capable of obtaining permanent improvement from it, and a certain economic level was imposed above which insured asthmatics could not receive this treatment. The age limits were between 5 and 55, and active pulmonary tuberculosis disqualified for treatment. A geographical study of the homes whence the patients, recruited from the whole of Sweden, came showed that low-lying and damp areas yielded a particularly high number of cases. The males represented 61 per cent. of the total, and the age incidence was highest between 15 and 25. The number of patients over 45 was comparatively small. There was a family history of asthma in about 20 per cent., of neurosis or psychosis in about 15 per cent., and of pulmonary tuberculosis in about 15 per cent. The asthma had begun before the age of 9 in 35 per cent., and before the age of 15 in every other case. It was very rare for the asthma to begin after 45. In about 50 per cent. a protracted attack of bronchitis was credited with starting the asthma, which in twelve cases had begun in connexion with pneumonia; and in nineteen with whooping-cough. Throughout the institutional treatment, or with the exception of the first few days, about 70 per cent. of the patients were completely free from attacks, and only in about 4 per cent. was no benefit obtained. An intermediate group was represented by the patients who became fit for work but were still subject to slight and occasional attacks. The group of twenty-one refractory cases included most of the eight patients with aspirin idiosyncrasy, and in this connexion the author notes that Storm van Leeuwen has also found that the asthmatic who is sensitive to drugs such as aspirin is apt to prove refractory to any and every treatment. The author's study did not include a follow-up investigation of the patients after the high altitude treatment ceased.

71 X-Ray Treatment of Leukaemia

F. BARDCHZI and P. MLEJNECKY (*Münch. med. Wschr.*, October 29, 1937, p. 1737) discuss the x-ray treatment of leukaemia. They base their experience on the observation of thirty cases of chronic myeloid leukaemia and twenty-five cases of chronic lymphatic leukaemia. They consider the acute myeloid leukaemia as somewhat akin to certain forms of septicaemia. For this acute leukaemia radiotherapy is useless; it does not even delay the early fatal end. But both myeloid and lymphatic leukaemia are favourably influenced by irradiation of the spleen, and in the case of lymphatic leukaemia the glands also. The authors begin the treatment with small doses of 20 to 30 r units, and increase the dose gradually according to the reaction of the patient. In some cases it may be necessary to increase the dose to 60, 120, or even 240 r units. The course of treatment is usually completed within three to six weeks. By that time the spleen should have shrunk to almost normal size, and the number of white blood cells should have been reduced to about 15,000. The authors do not aim at inducing a leucopenia. In case of recurrence the second course should be postponed for at least six to twelve months. In the later stages of the disease, when the leukaemic tissue has infiltrated the internal organs, the authors recommend the irradiation of the whole body with small doses of x rays. They believe that radiotherapy cautiously carried out not only makes the patient comfortable but actually prolongs life by months or possibly even years.

THE TREATMENT OF

Chilblains...

COLLOIDAL CALCIUM WITH OSTELIN. Prices (except Eire): Boxes of 6 x 1 cc. ampoules, 5/-; 12 ampoules, 8/6; 30 cc. bottles, 10/-

★ **OSTOCALCIUM TABLETS**
Prices (except Eire): Tins of 50, 2/3; 100, 4/-; 500, 12/6; 1,000, 17/6. All G.L. prices are subject to usual professional discount.

THE subcutaneous injection of Colloidal Calcium with Ostelin (5,000 international units of vitamin D and 0.5 mgm. of colloidal calcium per cc.) is almost a specific for chilblains. By this treatment even the worst cases can be helped through the winter in comfort and without disability, and in quite severe cases the skin circulation can be brought to a normal state. In many cases the pain, irritation and swelling subside after the first injection. The usual procedure is to give 2-3 injections of 1 cc. at 3 day intervals: but in chronic cases 6 such injections may be needed.

★ Treatment should include oral administration of calcium, preferably in the form of the highly assimilable Ostocalcium Tablets, each containing $7\frac{1}{2}$ grs. of calcium sodium lactate and 2½ grs. of calcium phosphate together with 500 international units of vitamin D.

stages. As a safe and efficient anaesthetic in obstetrics he recommends vinyl ether. This may be used in a closed machine, but in general practice is preferably given "open," in a mixture of one part of vinyl ether to three parts of ethyl ether.

Obstetrics and Gynaecology

77

Alexander-Adams Operation

U. MASSARI (*Arch. Ostet. Ginec.*, September-October, 1937, p. 427) summarizes from the literature 2,100 cases of mobile retroversion of the uterus treated by the operation of Alexander and Adams, with about 6 per cent. only of recurrences. He further records 113 cases operated on at Siena from 1929 to 1936; no recurrence had been observed within one to eight years of operation among the sixty-one patients who could be traced. Nine of them had conceived, gone to term, and had uncomplicated labours. He concludes that the Alexander-Adams operation is the best among round ligament operations, and that no advantage is to be gained from making the procedure intraperitoneal. The removal of the distal end of the ligament, which has been proved to be the weakest, is of undoubted advantage. The last of several separate sutures to the external oblique aponeurosis should include the pillars of the external abdominal ring and give firm fixation to the symphysis pubis.

78

Early Diagnosis of Pregnancy

A. STÁBILE and C. BECH-MORELLI (*Arch. Uruguay. Med.*, October, 1937, p. 393) mention two methods for the early diagnosis of pregnancy: (1) Bercovitz's pupillary reaction, and (2) Gilfillen and Gregg's intradermal pregnancy reaction. The pupillary reaction consists in anisocoria (usually miosis) after instillation of two drops of citrated blood into the conjunctival sac of one eye (1 c.cm. of the patient's blood is mixed with 0.2 c.cm. of a 10 per cent. solution of sodium citrate). The authors state that they have not had sufficient experience of this reaction to express any definite opinion. Gilfillen and Gregg's reaction consists in the intradermal injection of two or three drops of an extract of the anterior pituitary (gonadotropic hormone) into the skin of the anterior aspect of the forearm. The theory on which the reaction is based is that when the skin is already overloaded with gonadotropic hormone, as in pregnancy, the effect of the injection is negative, whereas in the absence of any such hormone in the skin the injection gives rise to a papule which rapidly increases in size and is surrounded by an erythematous zone. The reaction usually makes its appearance about a quarter of an hour after injection and persists for about one hour. The authors state that though some workers have apparently obtained a very high percentage of successes with this reaction, their own results in ninety-five cases were far from successful. They consider that this particular reaction has not yet advanced beyond the experimental stage, and cannot take the place of the Aschheim-Zondek and Friedman reactions in the diagnosis of pregnancy.

Pathology

79 Antiscorbutic Limitations of Synthetic Ascorbic Acid

A. ELMBY and E. WARBURG (*Ugeskr. Laeg.*, October 28, 1937, p. 1141) have investigated the reaction to a daily dosage of 300 mg. of ascorbic acid in twenty-nine patients showing a haemorrhagic diathesis (revealed by Göthlin's capillary test) and a low ascorbic acid content of the serum (Lund and Lieck test). After ten days of this treatment the haemorrhagic reaction of Göthlin was no longer demonstrable, and the ascorbic acid content of the serum was

restored to normal in twenty-six cases. In the remaining three cases no such improvement was observed, even when the oral administration of ascorbic acid was followed by the intravenous injection of 300 mg. of ascorbic acid daily for ten successive days. But when the three patients were given the juice of ten lemons daily for ten days the response was rapid. A characteristic feature of all three cases was intestinal disease which had lasted for several years. After giving details of these three cases the authors conclude that the absorption and retention of ascorbic acid require the presence in the body of a substance, a co-vitamin, which is evidently present in lemons and perhaps in small quantities in other articles of food, but is absorbed with difficulty by patients suffering from certain intestinal diseases. The authors are now investigating the possibility of this substance being identical with the vitamin P found by Szent-Györgyi.

80

Thyroid Tumours of the Ovary

According to H. O. NEUMANN (*Arch. Gynäk.*, 1937, 163, 3, 600), who has found thyroid tissue in some 10 per cent. of ovarian teratomata, it is possible in the majority of cases to recognize with the naked eye both thyroid and other organized tissues; so-called "pure struma ovarii," consisting solely of thyroid, has been described, but almost certainly after incomplete microscopical examination. Microscopically the same varieties of parenchymatous and colloid goitre are shown by ovarian as by cervical thyroid tissue; microscopical diagnosis is much more reliable than that based on biological tests such as estimation of blood-iodine or the Reid-Hunt reaction. It is exceptional for women bearing thyroid-containing ovarian teratomata to show clinical signs of thyrotoxicosis; four cases have been described, however, in the literature. To these Neumann adds a fifth—that of a woman, aged 27, with a pulse rate of 120, a systolic blood pressure of 170 mm. Hg, tremor, and a 40 per cent. increase in the basal metabolic rate; a cystic ovarian teratoma weighing 880 grammes and containing much solid colloid-containing thyroid tissue was removed. The signs of hyperthyroidism disappeared during convalescence, and pregnancy was not long delayed. Trapl has described a case of compensatory enlargement of the cervical thyroid following a similar operation.

81

Aetiology of Epidemic Hepatitis

T. THUNE ANDERSEN (*Acta med. scand.*, 1937, 93, 1-2, 209) notes that at present Denmark is the only country in which epidemic hepatitis has been made a notifiable disease, and that since 1928 the number and geographical distribution of the cases have been recorded under the national health insurance scheme. The fact that the sickness rate is about eight times greater in the country than it is in Copenhagen suggests that the disease is not spread by contact or droplet infection, but is more likely to be an alimentary infection. Noting that pigs suffer from a form of jaundice which resembles epidemic hepatitis in man, the author has compared the number of jaundiced pigs arriving at the abattoirs between 1930 and 1934 with the outbreaks of epidemic hepatitis in man in the same period. The correlation thus established is, in his opinion, indicative of a causal relationship between the jaundice of pigs and that of man. He suggests that the low sickness rate in Copenhagen and Aarhus is due to the fact that the control of the meat supplies of these two towns is more effective than elsewhere. In support of his opinion that jaundice in pigs is an infectious disease, the author gives an account of his own experiments, in the course of which he has succeeded in transmitting jaundice from one pig to four others, and from two of them to two more by feeding healthy pigs with jaundiced pig's liver. He concludes that veterinary opinion as to jaundice in pigs being a non-infectious disease is incorrect, and that the regulations governing the sale of pork from jaundiced pigs must be made more strict.

THE PHANTOMYST INSECTICIDE SPRINKLER

(Pro. Pat.)

This "delayed action" Sprinkler is used in connection with the latest method of Disinfestation of buildings with washed Heavy Naphtha. It can be set to operate at any time up to eleven hours after finally sealing the room. The Sprinkler distributes one gallon of Naphtha in about $1\frac{1}{2}$ minutes. MAW STEROTHERM

HOT AIR ELECTRIC AUTOMATIC STERILIZER

Patent, No. 427581

Maw Sterotherm Automatic Sterilizers have been installed in the London, Westminster and many other Hospitals, Surgeries etc., throughout the country and are functioning with the utmost efficiency. The special features of the Sterotherm ensure complete sterilization of Instruments, Dressings, Oils, etc., by the Hot Air method. It is the ideal unit where economy of space and outlay are essential.

May we send you details or arrange a demonstration?

SPECIAL FEATURES

- Efficient Sterilization.
- Automatic regulation of temperature.
- No supervision necessary while in use.
- Very small current consumption.
- Articles in apparatus remain sterile until required, as closure is bacteria-proof.
- Dressings quite dry after leaving Sterilizer.
- Convenient size—length 16½ in., diameter 9½ in.

PRICE £20

"LIVEROID"

BRAND

PREPARATION OF LIVER

"LIVEROID" is a concentrated preparation of the uncoagulated juice of liver, in combination with other blood and nerve-forming substances. Usefully prescribed for:—

Pernicious anæmia and all forms of megalocytic anæmia characterised by high colour index.
Normocytic or secondary anæmias due to loss of blood from any cause.
Microcytic anæmias in which iron therapy combined with liver is desirable.
General debility, neurasthenia or weakness.

"LIVEROID" is pleasant to take, and can be given in the form of an appetising beverage.

Literature supplied on application:

In Bottles, 3/6 and 5/9

OXO LIMITED, Thames House, Queen St. Place, London, E.C.4

SCIENCE NOW GIVES SENSIBLE VENTILATION

Indispensable in the doctor's waiting and consulting rooms—extracting the stale air without draughts.

Whereas fans merely circulate stale air, the ILG Extractor Ventilator gives adequate ventilation at minimum cost. Its use in Nursing Homes allows perfect ventilation with windows shut, thus precluding outside noise.

Adequate Ventilation. ILG Ventilators have been scientifically designed to give frequent changes of air without draughts. Suitable for every kind of room.

Economical to Run. The Ilgette model extracts 27,000 cubic feet of air per hour, consuming only 40 watts. The Ilgare extracts 45,000 cubic feet of air per hour, consuming only 70 watts. It can be installed in window or wall.

Illustrated is the Package model—easily operated by a pull at the nickel-silver beaded chain, of extreme reliability.

cv5-201

Puritan Tanneries Ltd., Runcorn, Cheshire.

THE ABSOLUTE COMFORT and security which the Deimel Underwear affords in the most trying climate is remarked upon by all its wearers. Those whose powers of resistance have been weakened by wearing unsuitable underwear derive new strength from Deimel Mesh Garments which absorb and eliminate perspiration quickly, and provide a dry climate about the body which enables the wearer to undergo extremes of heat and cold with comfort.

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President, THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from intractable mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special suites, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombiere treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for Biochemical, Bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm gardens and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is tennis-club in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM HOSPITAL FOR MENTAL DISEASES

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Occupational Therapy. Voluntary and Temporary Patients received.

Tel.: 64117. For terms, etc., apply to the Medical Superintendent.

WARM, DRY BEDS FOR OPERATION AND ACCIDENT CASES

In cases of sudden emergency and for everyday use, the "Thermega" Electrically-Heated Blanket is invaluable for providing warm, damp-free beds. Hospitals and Nursing Homes throughout the country use "Thermega." It is the one proven remedy for driving out dampness and ensuring warm beds at the turn of a switch.

The "Thermega" Electric Pad for local application is ideal for relief of pain and for replacing hot water bottles.

At all good stores, chemists, electricians; or from Thermega Limited, 51/53, Victoria Street, London, S.W.1.

SOUTH GLOUCESTERSHIRE (M.O.H.) JOINT COMMITTEE.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH

The Joint Committee invite applications for the above appointment from duly qualified and registered Medical Practitioners between the ages of 30 and 50, who, in addition to the qualifications prescribed by any Statute, are also registered in the Medical Register as holding a Diploma in Sanitary Science, Public Health or State Medicine.

The appointment will be subject to the provisions of the Local Government Act, 1933, the Sanitary Officers' (Outside London) Regulations, 1935, and the approval of the Minister of Health.

The person appointed will be required to perform all the duties imposed on a Medical Officer of Health under the relevant Acts and Orders, and will also be required to carry out such other duties as the Joint Committee may from time to time direct. He will be required to reside in one of the Areas concerned, and to devote his whole time to the duties of the office. He will not be permitted to engage in private practice.

The successful candidate will be required to commence his duties on April 1st, 1938.

The inclusive salary will be £800 per annum, together with a travelling allowance of £100 per annum. All fees receivable in respect of any duties must be paid into the Joint Committee's account.

The post will be designated for the purposes of the Local Government and Other Officers' Superannuation Act, 1922, in due course. The successful candidate will be required to pass a medical examination and to contribute towards any Superannuation Fund.

The Officer will be required to give three months' notice to terminate the appointment, which will be subject to the provisions of Section 110 of the Local Government Act, 1933.

The constituent Authorities of the Joint Committee consist of the Urban Districts of Kingswood and the Rural Districts of

and the total combined
as follows:
3,160
acres.

Applications, stating qualifications and experience, accompanied by copies of three recent testimonials, must be delivered to the undersigned not later than Tuesday, February 8th, 1938.

Canvassing is prohibited.

Council Offices, E. A. E. STEVENTON,
Kingswood, near Bristol. Clerk.
January 14th, 1938.

COUNTY COUNCIL OF THE WEST RIDING OF YORKSHIRE.

SCOTTON BANKS SANATORIUM.

Appointment of SENIOR ASSISTANT MEDICAL OFFICER AND DEPUTY MEDICAL SUPERINTENDENT.

The County Council of the West Riding of Yorkshire invite applications from registered medical practitioners (female) for the appointment of Senior Assistant Medical Officer and Deputy Medical Superintendent (resident) at the Scotton Banks Sanatorium, near Knaresborough, for women (100 beds) and children (100 beds).

Candidates should have previously held an appointment as House Physician or House Surgeon, and experience in Pulmonary and Non-pulmonary Tuberculosis and Anaesthetics will be an advantage. Salary £450 per annum, rising by annual increments of £25 to £550 per annum.

Further particulars and forms of application may be had from the undersigned, and applications, together with not more than three recent testimonials, must be sent to me not later than Monday, January 31st, 1938.

County Hall, J. CHARLES McGRATH,
Clerk of the County Council.
January, 1938.

CITY OF SHEFFIELD. CITY GENERAL HOSPITAL.

ASSISTANT MEDICAL OFFICER.

Applications are invited from duly qualified medical men for the appointment of ASSISTANT MEDICAL OFFICER (Grade I) in the above hospital. There are two vacancies.

Candidates should have previous hospital experience and, in addition, for one appointment should have special experience in obstetrics.

For the other appointment special experience in surgery is required.

Salary £350, rising by £25 to £450 per annum, with the usual residential allowances. The medical officers may be required for a time to live outside the hospital, and for this an allowance for subsistence will be paid.

These appointments are designated under the Local Government and Other Officers' Superannuation Act, 1922.

Applications, stating age, qualifications and experience, together with copies of three recent testimonials, should be sent to THE MEDICAL SUPERINTENDENT, City General Hospital, Sheffield, S. 1, on or before January 25th, 1938.

STAFFORDSHIRE COUNTY COUNCIL.

ASSISTANT MEDICAL OFFICER FOR MATERNITY AND CHILD WELFARE.

Applications are invited from fully qualified medical men or women for the post of whole-time Assistant Medical Officer for maternity and child welfare.

Candidates should have had at least three years' experience in the practice of their profession and special experience of practical midwifery and antenatal work subsequent to qualification. It is desirable that applicants should hold the Diploma of Public Health.

The salary will be at the rate of £600 per annum rising by annual increments of £50 to £800 per annum, subject to a deduction of 5 per cent established under the Local Government and Other Officers' Superannuation Act, 1922.

The successful candidate will be required to undergo a medical examination and produce a birth certificate. The appointment will be subject to three calendar months' notice on either side.

Forms of application may be obtained from the undersigned and should be returned by first post on February 3rd, 1938, together with copies of not more than three testimonials.

Candidates must state in their applications whether or not they are related in any way to any member of the County Council.

Canvassing, either directly or indirectly, will be a disqualification.

IRAQ GOVERNMENT. APPOINTMENT OF BRITISH SURGICAL SPECIALISTS.

The Iraq Government invite applications from British Medical and Surgical Specialists (male) for the following vacant appointments.

1. OBSTETRICIAN AND GYNAECOLOGIST.

Duties: To be Professor of Obstetrics and Gynaecology in the Royal College of Medicine, Bagdad, and Chief of the Unit of Obstetrics and Gynaecology in the Royal Hospital, Bagdad.

Salary: Iraq Dinars 150 per mensem.

2. EAR, NOSE, AND THROAT SPECIALIST.

Duties: To be Lecturer on Ear, Nose, and Throat diseases in the Royal College of Medicine, Bagdad, and Chief of one of the Units for these diseases at the Royal Hospital, Bagdad.

Salary: Iraq Dinars 120 per mensem. In special circumstances if it is considered that the candidate's qualifications and experience justify it a salary in excess of this amount, but not exceeding 150 Dinars per mensem, may be granted.

3. GENERAL SURGICAL SPECIALIST.

Duties: To act as Surgical Specialist in any hospital of the Iraq Health Service as required and to assist in the teaching of Surgery in the Royal College of Medicine, Bagdad, if required.

Salary: Iraq Dinars 120 per mensem.

Candidates must be experienced in operative work and must hold a Specialist's diploma in their branch of work, such as F.R.C.S., M.C.O.G., or D.L.O.

Age must not exceed 45 years. Successful candidates will be required to enter into contracts for a period of five years. Consultant practice is allowed provided that it does not interfere with the performance of official duties. The teaching at the Medical College is in the English language.

One Iraq Dinar is equivalent to one Pound Sterling. Salaries will be subject to Iraq Income Tax which is:—150 dinars exempt, the next 150 dinars subject to 6% tax, and the remainder of the income 9%.

Forms of application and copies of the Form of Contract can be obtained from the Iraq Minister, the Royal Iraq Legation, 22, Queen's Gate, London, S.W. 7. Particulars as to the Provident Fund, leave, and passage allowances are given in the Form of Contract.

No application can be considered unless received *on the prescribed form* not later than February 18th.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in April, 1938.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W. 1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than February 28th, 1938.

UNIVERSITY OF CAPE TOWN.

SENIOR ASSISTANT IN ANATOMY.

The University of Cape Town invites applications
for the post of Senior Assistant in the Department
of Anatomy; salary £800 per annum, rising by
annual increments of £25 to a maximum of £900
per annum.

Candidates must hold a medical qualification and
should have had previous teaching experience. The
successful candidate will be expected to undertake
research work in addition to his teaching duties.
Ability to teach in both official languages (English
and Afrikaans) will be a recommendation.

Applications must reach the Secretary, Office of
the High Commissioner for the Union of South
Africa, South Africa House, Trafalgar Square,
London, W.C.2 (from whom forms of application
(quadruplicate) and a memorandum giving the
conditions of appointment may be obtained), not
later than February 15th, 1938. Applicants, in
addition to submitting copies of testimonials, must
give the names of three referees, and must state the
earliest date on which they would be able to
assume duty.

UMTATA HOSPITAL BOARD.

SIR HENRY ELLIOT HOSPITAL.

APPOINTMENT OF SENIOR RESIDENT
MEDICAL OFFICER.

Applications are invited from qualified Registered
Medical Practitioners for the above-mentioned post.
The salary attached to this position, which is whole-
time, is at the rate of £600 per annum, plus free
house, water, light and sanitation. A double-
storied dwelling-house is shortly to be erected in
which the successful applicant will be required to
reside, but pending its completion he will be
allowed an amount of £10 per month in lieu of
quarters and incidental costs.

The successful applicant is to assume duty on
July 1st, 1938, and to enter into contract of service
for three years (which may be renewed), the first
year to be on probation.

The Hospital has 154 beds (22 European, 132
Native), but this accommodation will be increased by
approximately 60 beds in the near future. Duties
include assisting at operations, anaesthetics, radiology,
the general ward work of a resident medical
officer, lecturing to nurses, and the general super-
intendence of the whole Hospital.

Applicants to state full particulars of:

(1) Their Medical and, in particular, Radiological
and Surgical experience.

(2) Nationality, age, and whether married or
single.

(3) Whether fully conversant with both English
and Afrikaans

Applications, with copies of three recent testi-
monials and health certificate, must be lodged with
the undersigned not later than noon on March 15th,
1938.

Umtata, C. E. DEVAN,
Cape Province, South Africa. Secretary.

MEDICAL OFFICER to take charge of new
hospital, medical and surgical, village dispensaries
and public health.

Age between 30-40, British born.

Initial salary Rs. 1,400 per month, rising by
bi-annual increments of Rs. 50 per month to
Rs. 1,800 per month. (One rupee = 1s. 6d.)

Provident fund Rs. 150 per month. Agreement
in first place for five years. Leave after every
two years' service at rate of 45 days for each
year's service. Free passage on joining and once
in every four years when proceeding on leave.
Free furnished house and car.

Applications accompanied by copies of three
testimonials to be sent by Air Mail to THE
ADVISER, Bahrain Government, Bahrain, Persian
Gulf.

COUNTY OF THE CITY OF WORCESTER

ASSISTANT MEDICAL OFFICER (Female)

Applications are invited for the above appoint-
ment from women of not more than 35 years of
age, who are duly qualified Medical Practitioners
holding a Diploma in Public Health. The duties
will include work under the School Medical Service
and the Maternity and Child Welfare Service, and
experience in this work is desirable. Special ex-
perience in refraction and ante-natal work will be
an advantage.

The Officer appointed will work under the
direction of the Medical Officer of Health, and will
be required to assist him in other duties as directed.
The salary offered is £500, rising by annual in-
crements of £25 to £700, and the post is designated
for purposes of Superannuation.

Further particulars and a form of application
may be obtained from the Medical Officer of
Health, to whom applications should be returned
not later than January 29th.

Canvassing, directly or indirectly, will be a
disqualification.

laundry. Applications, stating when at liberty, etc.,
and qualifications, together with copies of recent
testimonials, to be addressed to the undersigned.

OLIVE FURNEUX,
Secretary

BURY INFIRMARY (LANCS) (127 Beds)

APPOINTMENT OF CASUALTY OFFICER (male).

A vacancy, at above, arises on the Resident Medical Staff about the end of February, and applications are invited for the post.

The Resident Staff consists of an R.S.O., a House Surgeon, a House Physician, and a Casualty Officer.

In addition to his duties in the Casualty Department, the Casualty Officer is also responsible for the In-patient and Out-patient work in connection with the Eye and Ear, Nose and Throat Department.

The appointment is for six months at a salary at the rate of £150 per annum, with board, residence and laundry, and the successful candidate will be expected to commence duties on or about February 26th.

Applications, stating age, qualifications and nationality, together with copies of three recent testimonials, are to be forwarded to the undersigned as soon as possible, endorsed "Casualty Officer." Further particulars may be had on application.

H. WILKINSON,
Superintendent.

BIRKENHEAD GENERAL HOSPITAL. (156 Beds)

Applications are invited for the following Resident (male) posts for the six months commencing April 1st, 1938:

SENIOR HOUSE SURGEON. Salary £150 per annum.

The above post is recognized by the Royal College of Surgeons of England for the six consecutive months' appointment in charge of general surgical patients required of candidates before admission to the final examination for the Fellowship.

SECOND HOUSE SURGEON. Salary £100 per annum.

HOUSE PHYSICIAN. Salary £100 per annum.

CASUALTY OFFICER. Salary £100 per annum.

All with board, residence and laundry.

Applications, stating age, nationality and qualifications, together with three recent testimonials, to reach the undersigned by February 20, 1938.

W. H. DANIELS, F.C.S.,
Secretary-Superintendent.

CARDIFF ROYAL INFIRMARY. (Associated with the Welsh National School of Medicine.)

Applications are invited for the post of **RESIDENT SURGICAL OFFICER.** Duties will include case record-keeping and teaching, and Surgical work under the direction of the Honorary Staff.

Candidates must be Masters in Surgery of a University of the United Kingdom, or Fellows of one of the Royal Colleges of Surgeons in the United Kingdom, and must have previously held a Resident Hospital post.

The salary will be at the rate of £200 per annum, with board, residence and laundry. The appointment is for one year, and the holder will be eligible to apply for reappointment and may retain office for three consecutive years.

Further particulars may be obtained from the Medical Superintendent, to whom applications (endorsed "R.S.O."), with not more than three testimonials (copies), must be sent by noon on Monday, January 31st, 1938.

By Order of the Council,
R. ARMSTRONG,
Medical Superintendent.

CARDIFF CITY MENTAL HOSPITAL, Whitchurch, Glam.

HOUSE PHYSICIAN (male), are not exceeding 30 years, required for above hospital (750 beds). Salary £200 per annum, with apartments, board, attendance and laundry. Six-monthly appointment, renewable for a further six months. The Hospital provides facilities for all modern psychiatric treatment, is equipped with Research Laboratories (biochemical and pathological) under a whole-time Director of Research, conducts out-patient clinics and is associated with the Welsh National School of Medicine for the teaching of Psychological Medicine.

Applications, together with copies of three recent testimonials, to be forwarded to the Medical Superintendent.

CLAYTON HOSPITAL, WAKEFIELD.

Applications are invited for the post of **HOUSE SURGEON** for six months (renewable) from February 12th, 1938. Candidates should be of British nationality, male, and single. Salary at the rate of £200 per annum, together with board, residence and laundry.

Applications, stating age, qualifications and experience, together with three recent testimonials, should be sent to the undersigned by January 28th, 1938.

T. F. MACKENZIE,
Superintendent and Secretary.

COUNTY MENTAL HOSPITAL, LANCASTER.

Applications are invited for the post of **ASSISTANT MEDICAL OFFICER (male).**

Candidates must be single and under 35 years of age. Commencing salary £541, rising by annual increments of £25 to £660, with further increase on promotion, subject to a deduction of 3 per cent. under the Asylum Officers' Superannuation Act. There are no emoluments.

The selected candidate will be required to live in the Hospital, and be provided with board, lodging, etc., for which a charge of £150 a year is made.

The possession of a Diploma in Psychological Medicine will entitle the Officer to an additional £50 per annum.

Applications, giving full particulars, with testimonials (copies only), should be forwarded to the Medical Superintendent on or before January 25th, 1938.

HULL ROYAL INFIRMARY. (365 Beds.)

Applications are invited from registered Medical Practitioners for the post of **HOUSE SURGEON (male)** to the Ophthalmic and Ear, Nose and Throat Departments, vacant February 12th.

Salary at the rate of £150 per annum, plus board, board and laundry. The post is recognized for the clinical work required in the regulations for the D.O.M.S. and D.L.O. The appointment will be for a period of six months, but will be determinable at any time by one month's notice on either side.

Applications, giving particulars of age, experience and nationality, together with copies of recent testimonials, should be addressed to the undersigned.

January 17th, 1938. R. J. CARLESS,
House Governor.

THE GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION, GLOUCESTER. (225 Beds—Five Residents.)

Applications are invited for the post of **RESIDENT SURGICAL OFFICER (male)**, salary at the rate of £150 per annum, with board, residence and laundry. Candidates must be fully qualified and unmarried and have held previous house appointments. The appointment is for twelve months, which may be extended.

Applications, stating age, qualifications and nationality, together with not less than three recent testimonials, should be received by the undersigned not later than Wednesday, January 26th.

The elected candidate will be required to enter upon his duties on Thursday, February 3rd next.

January 6th, 1938. F. J. SIMONS,
Secretary.

KNOWLE MENTAL HOSPITAL, FAREHAM, HANTS.

Applications are invited for the post of **JUNIOR ASSISTANT MEDICAL OFFICER.**

Applicants should be male and single and under 35. The salary is £350, rising by yearly increments of £25 to £450, with board, lodging, washing and attendance, valued at £150.

The possession of a Diploma in Psychological Medicine entitles the holder to an extra £50 p.a.

The salary is subject to deduction under the Asylum Officers' Superannuation Act, 1907.

Applications, stating age and all particulars, accompanied by copies of three recent testimonials, should be sent to the Medical Superintendent not later than February 5th, 1938.

January 18th, 1938.

SURREY COUNTY COUNCIL.**ASSISTANT MEDICAL OFFICER.**

Applications are invited for the appointment of an Assistant Medical Officer (female). Applicants must possess a qualification in Public Health, and have had experience in the Medical Inspection of School Children, in Maternity and Child Welfare, and in the examination and certification of mentally defective children. The officer appointed will be required to undertake such other Public Health duties as may be allocated to her. She will be on the staff of the County Medical Officer of Health, must reside in the County of Surrey, and devote her whole time to the work. Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointment will be subject to the approval of the Ministry of Health and of the Board of Education, to the successful candidate passing a medical examination, to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the Staffing Regulations of the Council, which provide, *inter alia*, that appointments may be determined at any time by three months' notice.

Applications, stating age, qualifications and experience together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, County Hall, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any enquiries relating to the appointment should be addressed.

Last day for receipt of applications, Wednesday, January 26th, 1938.

Canvassing, directly or indirectly, will disqualify.

DUDLEY AUKLAND,

County Hall, Clerk of the County Council.

STORY OF A GREAT HOSPITAL THE ROYAL INFIRMARY OF EDINBURGH, 1729-1929

by

A. LOGAN TURNER, M.D., LL.D.

Royal 8vo. 408+XVI pages, photogravure frontispiece and 34 illustrations, 4 plans.

OLIVER & BOYD, TWEEDDALE COURT, EDINBURGH.

APPOINTMENTS.—Contd.

THE HOSPITAL FOR SICK CHILDREN.
Great Ormond Street, London, W.C.1.

Applications are invited for the post of ASSISTANT PATHOLOGIST (male).

Candidates, who must possess a legal qualification to practice, are required to send in their applications, addressed to the Secretary, accompanied by copies of not more than three testimonials, given specially for the purpose, before 12 o'clock on Monday, January 31st, 1938.

The appointment is made for one year, and is non-resident.

Salary £400 per annum, with facilities for Private Pathological Practice.

The selected Candidate will be required to take up his duties not later than February 16th, 1938, preferably earlier.

All Candidates must be in attendance to appear before the Joint Committee on Wednesday, February 2nd, 1938, at 4.45 p.m.

Forms of application, copy of the rules, and details of the appointment will be supplied on application to the undersigned.

HERBERT F. RUTHERFORD,
Secretary.

THE HOSPITAL FOR SICK CHILDREN.
Great Ormond Street, London, W.C.1.

There are vacancies for two ANAESTHETISTS. Candidates must be registered medical practitioners and be prepared to take up their duties at an early date.

The appointment is for one year, but is renewable and carries with it an honorarium of £15 15s. per annum, and an allowance of £6 6s. to provide a substitute during annual leave.

Candidates are invited to send in their applications, addressed to the Secretary, with copies of not more than three testimonials written specially for the purpose, before 12 o'clock on Monday, January 31st, 1938, and must appear personally before the Joint Committee at their Meeting on Wednesday, February 2nd, 1938, at 4.45 p.m.

Forms of application and copies of the rules are obtainable from the undersigned.

HERBERT F. RUTHERFORD,
Secretary.

THE HOSPITAL FOR SICK CHILDREN.
Great Ormond Street, London, W.C.1.

Applications are invited from registered medical practitioners for the post of CASUALTY MEDICAL OFFICER. Salary £175 per annum. Duties to commence on February 7th, 1938.

The appointment is a half-time one and non-resident, tenable in the first instance for six months. Applications must be received by noon on Monday, January 31st, 1938, and candidates must be prepared to attend for interview at the Hospital on Wednesday, February 2nd, 1938, at 4.45 p.m.

Full details of the appointment and forms of application are obtainable from the undersigned.

HERBERT F. RUTHERFORD,
Secretary.

EASTERN DISPENSARY.
Lennox Street, E.1.

Applications are invited for the post of PHYSICIAN at this institution, to attend on Wednesday afternoons at 2.30. Candidates must be members of a Royal College of Physicians in the United Kingdom or Graduates in Medicine of a recognized British University. There is an honorarium attached to the post.

GEORGE W. JISLEY,
Secretary.

THE QUEEN'S HOSPITAL FOR CHILDREN.
Hacking Road, London, E.2.

HOUSE SURGEON required March 1st, 1938.
CASUALTY OFFICER required March 1st, 1938.
Some Orthodontic work additional.

Six months' appointments. Salary at the rate of £100 per year, with board, lodging and laundry. Applications must be made on forms to be obtained from the undersigned, and must be sent in, with copies of not more than four testimonials, on or before February 4th, 1938.

CHARLES H. BESSELL,
January 1st, 1938. Secretary

THE LONDON CHEST HOSPITAL.
Victoria Park, E.2.
(Bus, Tram and Rail, Cambridge Heath L. and N.E. Railway)

A vacancy for a HOUSE PHYSICIAN (male) will occur on March 1st. Six months' appointment. Salary at the rate of £100 per annum. Board, residence and laundry provided.

Applications, with copies of testimonials (three), should be sent to the Secretary on or before Monday, January 31st, 1938.

THE WEIR HOSPITAL.
Grave Road, Balham, S.W.12.
(50 Beds.)

SENIOR and JUNIOR RESIDENT MEDICAL OFFICERS (male, unmarried) required at once. Candidates must be fully qualified and fully registered. Salary £250 and £150 respectively, with board and residence and laundry.

Applications, with copies of testimonials, to be sent to the Secretary, from whom further information may be obtained.

KING'S COLLEGE HOSPITAL.

The Committee of Management invite applications for the post of ASSISTANT PHYSICIAN. Applications, with copies of three testimonials, should be sent before February 8th, 1938, to the House Governor, King's College Hospital, Denmark Hill, S.E.5, from whom particulars of the duties may be obtained. Candidates must be Members or Fellows of the Royal College of Physicians of London.

Practices and Partnerships for Disposal (continued).

25 W. OF ENGLAND.—Old-established middle-class PRACTICE, about £1,400 p.a., in good town. Selected panel about 300. Visits 5/- to £1 ls. medicine extra. Very convenient and well-situated detached non-basement house (7 bedrooms), with nice garden and large garage, to rent. Premium one and a-half years' purchase.

26 WESTERN AUSTRALIA.—Non-dispensing PRACTICE in chiefly dairy farming district. Receipts average £1,815 p.a. House containing 6 main rooms, etc., and about four acres of grounds. Price £1,000 cash, or rent £100 p.a. Excellent climate. District rapidly progressing. Local hospital. Premium £1,250.

27 S. OF ENGLAND, Important Town.—PRACTICE averaging £1,000 p.a., exclusively physio-therapy. Fees 10/6 to £1 ls. Scope for X-ray work. Prospect of appointment on hospital staff. Premium to include certain equipment, £1,250.

28 EASTERN COUNTIES.—Country PRACTICE, averaging £1,750 p.a., within easy distance of county town. Panel 1,070. Good house (in 2½ acres) with 7 bedrooms, etc., garage, company's water and main drainage. Price £2,000 freehold. Premium two years' purchase.

29 LANCs.—Well-established non-panel PRACTICE, averaging over £4,000 p.a., in manufacturing town. House with 5 bedrooms and surgery premises with separate entrance, large garage and good garden, for sale. Price £2,500 freehold. Premium £6,000 or near offer.

30 S. COAST.—PARTNERSHIP in mixed PRACTICE, averaging £2,800 p.a., in seaside resort. Panel about 2,000. Semi-detached house (5 bedrooms, etc.), with good garden, for sale or rent. Excellent hospital. Scope for major surgery. Premium one-half share two years' purchase.

31 W. OF ENGLAND Inland Watring Place.—Old-established good-class easily worked PRACTICE. Receipts past year, £722. No panel. Practically non-dispensing. House with 6 bedrooms, etc., large garage and small garden, to rent on lease. Premium £1,000.

32 LONDON, E.I.—Old-established PRACTICE of about £800 p.a., including appointments about £150 p.a. and panel 1,300. Good house (6 bedrooms, etc.), to rent or purchase. Very good scope for increase. Premium £1,600, to include contents of surgery and waiting room, etc.

33 NORTHERN IRELAND.—Middle and working-class PRACTICE in suburb of important seaport. Receipts past year, £963. Panel nearly 1,200. Well-situated house (5 bedrooms), garage, etc., to rent. Practice capable of expansion. Premium £1,400.

34 HOME COUNTY.—PARTNERSHIP in country town Practice, averaging over £4,000 p.a. (increasing), within 25 miles of London. Good appointments and panel about 2,000. Suitable house obtainable. Incoming partner should be aged about 30, must possess F.R.C.S. and have had one year's P.G. work. Good hospital. One-fourth share at first at two years' purchase.

35 MIDLANDS.—Unopposed country PRACTICE in very pleasant hunting district. Cash receipts last year, £1,097, including good appointments and panel about 500. Well-built house (5 bedrooms, etc.), with good garden and garage. Main electric light and water supply. Price £1,100 freehold. Golf, etc. Premium £1,600.

36 S. COAST, popular seaside resort.—Small good middle-class non-dispensing PRACTICE, £350 £400 p.a. No panel. One appointment worth £50 p.a. Maisonette (3 bedrooms, etc.), to rent at £160 p.a. Premium £500.

37 MIDLANDS.—Easily worked PRACTICE in very attractive village about 70 miles from London. Cash receipts, 1937 (to November 25th), £696. Panel 500. Detached modern house (4 bed and dressing-rooms), gas, electricity and main drainage, garden over an acre. Price freehold, £1,500. Premium one and a-half years' purchase, to include stock of drugs.

38 AUSTRALIA.—PRACTICE in small township in Victoria. Receipts last year, £890. Specially built house to rent at £80 p.a. Good climate. All kinds of sport. Premium £500 English currency, including drugs and dispensary fittings.

39 SURREY.—PARTNERSHIP in sound old-established, and steadily increasing Practice averaging £4,445 p.a. in outlying residential suburban district. Panel 2,000. Visits 3/6 to 2/1-. Suitable house obtainable. Premium for share of 11/39ths £2,500.

40 LONDON, E.—Middle-class PRACTICE over £2,400 p.a., in outlying district. Panel 2,876. House (4 bedrooms), in excellent repair, with garage and garden, for sale. Premium two and a-quarter years' purchase.

41 S. COAST.—PARTNERSHIP in Ophthalmic Practice, about £1,700 p.a. One-half share would be sold to suitable man (who must possess the D.O.M.S.) at two years' purchase. Good scope.

42 N.E. COAST.—Old-established and easily worked middle-class PRACTICE, over £1,150 p.a., in seaport town. No panel. Residence facing sea, for sale. Premium (to include furnishings and fittings of consulting rooms, small X-ray plant, etc.), £1,030.

43 ITALIAN RIVIERA.—Small good-class non-dispensing season PRACTICE. Further details on application.

44 BRISTOL.—PARTNERSHIP in increasing Practice in growing suburb. Cash receipts past 12 months, £2,125. Panel 2,200. House, with 4 bedrooms and surgery accommodation, to rent at £60 p.a., also branch surgery. Scope. Premium one-half share £2,000, to include share of drugs, etc.

45 S. WALES.—Steadily growing middle-class PRACTICE doing about £500 a year in residential village, easy distance of large town. Modern semi-detached house (5 bedrooms), garage and garden. Price £1,350 leasehold. Scope. Premium one year's purchase.

46 SEASIDE TOWN, under an hour from London.—PARTNERSHIP (one-half share) in chiefly middle-class Practice, over £4,000 p.a., Panel 650. Corner house (5 bed and dressing-rooms), on main road, for sale. Scope for increase. Premium two years' purchase.

47 E. MIDLANDS.—Country PRACTICE, averaging nearly £650 p.a., in pleasant village. Panel 500. Charming stone-built house (6 bedrooms), central heating, electric light, power and main water, garage, and garden, about one and a-half acres, for sale. Scope. Premium two years' purchase.

48 LONDON, S.W.—Well-established Medical Woman's PRACTICE in outlying suburban district. Receipts average £960 p.a. No panel. Purchaser could have use of surgery premises, living accommodation and services by arrangement. Premium one and three-quarter years' purchase.

Purchasers can raise additional capital for the purchase of approved practices or shares.
Particulars will be forwarded on application.

FULL TERMS ON APPLICATION

Practices and Partnerships for Disposal.

Full Particulars sent free.

1 SURREY.—PARTNERSHIP in old-established PRACTICE, averaging over £2,800 p.a., in outlying suburban district on the Thames. Small panel. Visits 5/- upwards. Outgoing partner's house (5 bedrooms, etc.), could be purchased if desired. One-third or possibly larger share at two years' purchase.

2 MIDLANDS, Cathedral City.—Old-established non-dispensing PRACTICE, averaging £1,550 p.a. Small panel. Visits 6/- to 10/6. Convenient house (about 6 bedrooms), in best residential part to rent at £65 p.a. Excellent prospects for one experienced in clinical pathology. Premium one and a-half years' purchase.

3 DEATH VACANCY.—CUMBERLAND.—Old-established good-class non-dispensing PRACTICE, over £700 p.a., in rapidly growing town. No panel. Large house for sale or rent. Good scope.

4 S. OF ENGLAND.—SURGICAL PARTNER required in good-class Practice in first-rate residential district. Applicant should be aged 30/35 or thereabouts, must hold the English Fellowship and be prepared to do some general practice. Modern up-to-date hospital. Share about £1,000 p.a. at first at two years' purchase.

5 BRITISH WEST INDIES.—SURGICAL PRACTICE in favourite town. Cash receipts, 1937, £1,900. Fine opportunity for experienced surgeon. Well-equipped nursing homes, X-ray and laboratory facilities. Rent of consulting rooms £5 monthly, and house £12 monthly. All kinds of sport. Premium £800.

6 LANCASHIRE COAST.—NUCLEUS OF PRACTICE, averaging £245 p.a., offering excellent scope for increase. Not much panel. Good house (5 bedrooms), for sale. Suit either medical man or woman. Premium £500, to include drugs, instruments, etc., etc.

7 EALING.—PRACTICE in rapidly developing district. Cash receipts, 1937, £510. Panel 710, increasing. Small corner house (3 bedrooms), with garage and garden. Rent £78 p.a. Premium £750.

8 S.E. COAST.—Old-established middle and working-class PRACTICE, about £950 p.a., in favourite summer resort. Clubs worth about £130 and panel about 1,490. Detached corner house (5 bed and dressing-rooms), with large garage and about half-acre of garden, for sale. Scope. Premium one and three-quarter years' purchase.

9 MIDLANDS.—Old-established middle and upper-class non-dispensing PRACTICE, about £1,200 p.a., in prosperous town. No panel. Visits 7/-. House with 3 bedrooms, etc., for sale or rent. Scope. Premium one and a-half years' purchase.

10 N. WALES.—Sound old-established PRACTICE, about £1,500 p.a., in industrial village with beautiful surrounding country. (Appointments and panel return about £1,000 p.a.) Detached house (4 bedrooms), garage and garden. Price freehold, £2,000. Premium two years' purchase.

11 LONDON, N.W.—Old-established PRACTICE doing over £1,100 in residential district under ten miles from Marble Arch. Select panel 300. House (5 bedrooms), with large garden and garage. Price freehold, £3,250, or rent £150 p.a. Scope. Premium two years' purchase.

12 NEW ZEALAND.—Eye, Ear, Nose and Throat PRACTICE in a most important commercial city. Cash receipts last year, £2,277. Expenses light. Premium £2,460

cash or £2,600 terms (English currency). Purchaser should be at least 30 years of age with experience.

13 SEASIDE TOWN, within an hour of London.—Very old-established PRACTICE about £625 p.a. Panel about 300. Nice detached house (5 bedrooms), with large garage and garden, for sale or rent. Good scope. Premium £1,000.

14 DEATH VACANCY.—SOMERSET.—Old-established PRACTICE in village situate at foot of the Mendips. Cash receipts, 1937, £345, including £30 from clubs, etc., and panel of 318. Newly built detached house in acre of ground, with 4 bedrooms, etc. Large garage. Central heating. Electricity. Rent £75 p.a.

15 S. MIDLANDS.—Country town PRACTICE of over £1,100 p.a. Small club and panel, 775. Visits 4/- to 10/6, medicine extra. House with main water, gas and electricity, 4 bedrooms, garage and garden. £40 p.a. on lease. Premium one and three-quarter years' purchase.

16 EASTERN COUNTIES.—Very old-established PRACTICE, averaging £2,600/£2,700 p.a., in market town in agricultural district. Panel over 2,350. Large well-built modern residence with garage and good garden, to let. Premium two and a-quarter years' purchase.

17 DEATH VACANCY.—LEYTONSTONE.—Old-established mostly working-class PRACTICE, doing about £600, in populous district. No panel, but ample scope in this direction. Nine-roomed house for sale.

18 BRITISH WEST INDIES.—Increasing PRACTICE in first-rate town. Receipts last year, £1,750. Good house with ample accommodation, garage and good garden, for sale or rent. Ideal climate. Good society and sport. Scope for surgery or V.D. Premium £1,500, to include drugs, etc.

19 LONDON, S.W.—Medical Woman's PRACTICE in outlying suburban district. Receipts past year, £200. Capable of increase by one residing on premises. Panel 110. Rent of consulting and waiting rooms, £30 p.a.

20 YORKS (N. RIDING).—Well-established country PRACTICE near small market town. Receipts, 1937, about £1,000. Panel 480 (approx.). Appointments £60. Fees 2/6 to £1 1s. Good house with 5 bedrooms, 3 reception rooms, etc., good garden and field, £65 p.a. Premium two years' purchase.

21 S. WALES.—Old-established PRACTICE, £765 p.a., in country district near coast. Appointments worth nearly £100 p.a. and panel about 360. Specially built house (5 bedrooms, etc.), with garage and garden, for sale. Very good prospects of increase. Prem. one and a-half years' purchase.

22 INDUSTRIAL TOWN in the WEST OF ENGLAND.—Old-established and steadily increasing PRACTICE, averaging over £1,800 p.a. Panel about 560. House to rent. Premium £1,600.

23 LONDON, S.E.—Medical Woman's PRACTICE doing about £300 p.a., in suburban district. No panel. Plenty of scope. Semi-detached corner house. Price £750 or might be let. Could be increased by one giving more time to practice. Premium one and a-half years' purchase.

24 S.W. OF ENGLAND.—Country PRACTICE, averaging £2,500 p.a., easy distance of coast (appointments and panel return about £650 p.a.) Large house (3 reception, 6 bedrooms, etc.), in grounds of four acres, including orchard. Price £3,200. Hunting golf, etc. Premium one and three-quarter years' purchase.

Pain...
The Perfect Misery
 MILTON

Veganin Tablets offer a synergistic combination of three drugs with differing points of action, with the result that prompt and complete analgesia follows their use.

Veganin Tablets are not advertised to the public.

Supplied in tubes of 10 and 20 ; boxes of 100, 500 and 1,000 for dispensing.

A supply for clinical trial sent on request.

WILLIAM R. WARNER
 & CO., LTD.
 POWER ROAD · CHISWICK
 LONDON · · · · W.4

THE PROBLEM OF PAIN

To the physician pain is just a symptom, an alarm signal; but to the patient it is a very real affliction which eclipses all else. Once pain has served as a guide to diagnosis, Veganin will be found effective as a means for its prompt elimination.

Veganin affords quick and lasting relief. Unlike morphine with its peril of addiction, Veganin may be given indefinitely without risk of habit formation. Veganin does not cause drowsiness; it merely obliterates the pain and soothes the nervous system.

Severe Pain calls for Veganin

NEW BOOKJUST READY**ATLAS OF SKELETAL MATURATION**By **T. WINGATE TODD, M.B., Ch.B. (March), F.R.C.S. (Eng.)**

Demy Quarto, 75 Radiographic Plates of the Hand.

Cloth.

Price 31s. 6d. net.

This atlas contains 75 half-tones of roentgenograms selected as typical of the successive stages in ossification in the hand of boys and girls from three months until the date in adolescence when all epiphyses are united. There are more than a hundred pages of text dealing with general problems involved in the study and specific problems of the hand.

NEW (FIFTH) EDITIONNEXT WEEK**OPERATIVE GYNECOLOGY**By **HARRY STURGEON CROSSEN, M.D.,** and **ROBERT JAMES CROSSEN, M.D.****FIFTH EDITION, ENTIRELY REVISED AND RESET.**

Large Octavo, 1,076 pages, with 1,264 Illustrations including 3 Coloured Plates.

Cloth.

Price 52s. 6d. net.

The six years since the last edition of this work constitute a period of unusual activity in searching out the fundamentals of gynecologic physiology and structure and in applying such knowledge to the cure of diseased conditions. This intensive study has extended also to our therapeutic resources giving a much better understanding of their possibilities. This new edition has been extensively rearranged and rewritten to cover this new knowledge. About 200 new illustrations have been added.

NEW (SECOND) EDITIONJUST OUT**THE MANAGEMENT OF
FRACTURES, DISLOCATIONS AND SPRAINS**By **JOHN ALBERT KEY, B.S., M.D.,** and **H. EARLE CONWELL, M.D., F.A.C.S.****SECOND EDITION, REVISED AND ENLARGED.**

Large Octavo, 1,246 pages, with 1,222 Illustrations.

Cloth.

Price 52s. 6d. net.

A complete account of modern ideas and methods which can be depended upon to lead correctly in the proper care and management of all types of fractures, dislocations and sprains.

"A very comprehensive work to which practitioners will not refer in vain."—*British Medical Journal*.

NEW BOOKJUST OUT**THE ESSENTIALS OF PHARMACOLOGY, MATERIA
MEDICA AND THERAPEUTICS FOR MEDICAL STUDENTS**By **D. M. MACDONALD, M.D., F.R.C.P.E.**

Fcap Octavo, 279 pages.

Cloth.

Price 7s. 6d. net. (Postage 4d.)

The essential idea which suggested an addition to an already large number of text-books is to impress on the student the widest and more practical knowledge of pharmacy and materia medica, in order to cultivate intelligent prescriptions on the one hand, and to avoid slavery to proprietary preparations and stereotyped formulae on the other.

SAFE MILK...

Milk that is pure is full of blessings. Doubtful milk is a menace. With Nestlé's, care and cleanliness begin at the very beginning. Not only the farms but the feeding is sternly supervised. In the snow-white condenseries down in the shires, the fresh meadow milk is handled like something precious. Rich with all its cream and goodness it is sealed beyond reach of danger. No harm, seen or unseen, can come to it. It is milk as it should be—utterly pure. Safe, sealed, signed with a name you can trust.

NESTLÉ'S MILK

A Guaranteed Service for Deaf Patients

- 1 An audiometer test to determine the amount of hearing loss.
- 2 Adaptation of a suitable aid to conform to individual requirements.
- 3 A trial of the selected aid at home, without obligation to purchase.
- 4 Submission of a full report to the doctor concerned, enabling him to supervise the trial.
- 5 A guarantee covering any alterations made necessary by changing aural conditions.
- 6 Every reliable type of hearing aid available, Valve amplifiers, Air conduction, Bone conduction, and full non-electric range.

Members of the Medical Profession are invited to make full use of the service offered, with every confidence that genuine assistance will be rendered in the selection of a suitable hearing aid.

COLLOIDAL... ASSIMILABLE... PALATABLE

Ovoferriin Brand Colloidal Iron Tonic, the palatable blood builder, is stainless, odourless, non-astringent. It is iron in its most minute, most useful colloidal subdivision. Ovoferriin does not constipate; it does not affect the teeth or stomach; rather, it stimulates the jaded appetite and often aids in intestinal peristalsis. Many physicians have found it to be the only preparation simple, agreeable and effective enough for long term iron feeding. Ovoferriin contains no flavouring or sugar; it is economical to use and an excellent vehicle. - Write for free professional sample.

OVALTINE

AN AID TO HEALTHY DEVELOPMENT

MODERN medical research makes it increasingly clear that abnormalities of form, mental defects and even permanent constitutional weakness, are often a direct result of failure to obtain in infancy a diet adequate to the physiological needs of the organism. The basic necessity, therefore, in constructing the dietary of the infant and growing child, is to ensure one that is complete in all the essential food elements.

"Ovaltine" finds one of its most valuable applications in this direction. Composed of the nutritive constituents of fresh, full-cream milk, eggs and malt, in well-balanced proportions, it supplies calcium, phosphorus, vitamins and other accessory food factors, and its regular addition to the ordinary diet of the child renders this safe and adequate.

"Ovaltine" is so delicious and easily digested that it can be prescribed with complete confidence for children of all ages. "Ovaltine" is easily prepared and is most economical.

A liberal supply for clinical trial sent free on request.

Laboratories and Works: KING'S LANGLEY. HERTS.

the scientific contraceptive

MIL-SAN is a bland, non-injurious, spermicidal jelly independent of variable physiological conditions of moisture or temperature. Since there is nothing to melt, dissolve or foam, MIL-SAN is immediately effective.

The formula of MIL-SAN is based on biological principles in harmony with the natural chemical and bactericidal balance of the vagina. Its spermicidal efficiency is due to: (a) A low pH secured by the reinforcing action of several acids which ensures the immediate immobilization and death of spermatozoa, despite the buffering action of the seminal fluid; (b) A low surface tension which causes the jelly to spread rapidly and to penetrate the rugae of the vaginal and cervical mucous membrane; (c) A degree of viscosity which ensures that it shall adhere to the cervix and upper vaginal tract and fornices, forming a chemical barrier preventing the penetration of spermatozoa into the os uteri.

The method of applying the jelly is simple, hygienic, and proof against carelessness. Each application of 7 c.c. is contained in a specially

made strong glass tube sealed at one end with a cork, at the other by a hard wax plug. In use the cork is removed, a bulb fitted behind the wax plug, and the tube inserted. Compression of the bulb forces the wax plug down the tube and ejects the contents. The empty tube, which is thrown away, proves the application and ensures the quantity. There is nothing to fill, nothing to clean. Each application is hygienic and complete.

MIL-SAN does not deteriorate and is not affected by climatic conditions.

There are no contra-indications to the use of MIL-SAN with a dependable condom or a properly fitted occlusive pessary. It is only by such combined use that the consequences of misuse of one or other of the methods can be minimized and the maximum practicable security obtained. MIL-SAN is on the N.B.C.A. Approved List for use with a cap or condom.

Literature setting out the ingredients and full particulars, together with a box of specimen tubes for examination, are sent on request to members of the medical profession.

The Oral Treatment of Gonococcal Infections

Sulphonamide-P B.D.H. (sulpi.anilamide), introduced originally for the treatment of hæmolytic streptococcal infections, has been found to be effective also in many other infections including gonococcal infections.

Somewhat larger doses are required in gonorrhœa (up to 4 or 5 grammes daily) than in less refractory conditions.

Complete remission of clinical symptoms of infection has been reported 5 or 6

days after the beginning of the treatment, but the treatment must be continued for some time after this remission and cure should not be pronounced complete until stringent tests have proved negative over a considerable period.

Care must be exercised in administration, and the drug must be discontinued if cyanosis is produced. Cytological and spectroscopic examinations of the blood two or three times weekly are desirable.

Large Bowel Infections

THE use of ordinary purgative agents in chronic colitis and other inflammatory conditions of the large bowel is to be avoided on account of their tendency to increase existing spasm of the musculature and to aggravate inflammation of the mucosa.

"Cristolax" is the ideal agent with which to "clear" the bowel in such conditions. Its routine use diminishes mechanical friction while exerting a beneficial soothing effect. The formation of local areas of stasis behind bands and constrictions is successfully avoided.

"Cristolax" combines 50 per cent. of the purest medicinal paraffin of correct viscosity with "Wander" Dry Malt Extract. This palatable, effective, yet harmless intestinal lubricant is free from oily or disagreeable taste, and its crystalline form ensures easy administration.

M 25A

THE PHYSIOLOGICAL VALUE OF THE BANANA

III. Ash or mineral matter: The amount of ash (0.8 per cent average) is high for a fruit. It is alkaline, a point to be remembered in connection with intestinal weakness.

Small quantities of iron, copper and iodine are also present.

The iron content averages 6.4 parts per million, a satisfactory amount for a fruit. The presence of a minute amount of copper assists the due assimilation of the iron into the blood.

The trace of iodine, being more readily assimilable when normally present in a food than when added in the form of a salt, has its full beneficial action upon the thyroid gland.

N.B. Therapeutically, the banana is most valuable when fully ripe. In the fully ripe banana the soluble sugars evolved are approximately 9 per cent. cane-sugar and 4 to 5 per cent. each of glucose and fructose. A banana is ripe when all green has disappeared from the skin and brown spots have formed on the yellow surface.

DēCROSE

(GLUCOSE WITH VITAMIN D)

Dēcrose is a preparation of pure Medicinal Glucose with Vitamin D and Calcium Glycerophosphate.

Recommended in the treatment of: Debility, Malnutrition, Anorexia, Cyclical Vomiting in children, and in Convalescence.

Dēcrose is especially suitable for expectant and nursing mothers and growing children.

or from the
WHOLESALE AND
EXPORT DEPARTMENT

*Extract from the British
Medical Journal, 1936, i, 954*

**Idiopathic and Secondary
Hypochromic Anæmia.**

"Ferrous chloride is the most efficient, probably because it is the form into which most of the available iron is converted in the stomach before absorption. A total daily dose of 9 to 18 grains of stabilized ferrous chloride (Boots), made up into capsules of 3 grains each (that is, one to two capsules thrice daily after meals), is sufficient for the most severe degrees of hypochromic anæmia. In this form it maintains its ferrous condition very well."

BOOTS PURE DRUG CO. LTD. NOTTINGHAM, ENGLAND.

Your patient . . .

Food must obviously be restricted; yet some stimulating effect on digestion is desirable to maintain strength. Thirst is a problem. . . .

Brand's Essence does not cause thirst. And you will appreciate other reasons why this unique stimulant is of value to your patient. Brand's will not strain the most enfeebled system because it precipitates no solids and contains no irritants. A lively flow of the gastric ferments is aroused, but excess acid is effectively dealt with through protein-adsorption. Easy assimilation gives quick effect to Brand's potent protein-sparing properties.

BRAND'S CHICKEN OR BEEF ESSENCE

is never contra-indicated

BRAND & CO., LTD., SOUTH LAMBETH ROAD, LONDON, S.W.8

An Almost Exact Reproduction of Mothers' Milk

REMARKABLE CLINICAL RESULTS

INTERESTING CASE-HISTORIES FROM OVER TWO HUNDRED PHYSICIANS

KARO, a natural blend of soluble carbohydrates, has for many years been widely used abroad for children, pregnant mothers and invalids, and especially as a means of modifying cow's milk and milk powders for artificially-fed infants.

An eminent doctor writes: "We have found it (Karo) the most satisfactory form of carbohydrate in the feeding of normal and most sick infants."

A few months ago a number of physicians in this country were sent samples of Karo, and asked to report on it.

Over two hundred reports were received, giving case-histories of successful results obtained with Karo in the treatment of premature infants and of infants and children suffering from marasmus, biliousness, indigestion and nutritional disorders.

Costs about 1½d. a day

A 1 lb. tin of Karo, costing 1/3, provides a ten days' supply for a three-months-old baby—a cost of about 1½d. a day. The price of the 2 lb. tin has recently been reduced to 2/6.

Analysis of Karo

	per cent.

Mistol

MISTOL DROPS act as a local anæsthetic to the inflamed mucous membrane, thereby affording relief in all the distressing symptoms of common cold. The volatile substances contained in Mistol free the congested mucus, relieving the characteristic stuffiness and difficulty of correct breathing. **MISTOL** is extensively prescribed in most acute conditions affecting the mucous membranes of the nose and throat.

PHARMACEUTICAL SPECIALITIES (MAY & BAKER) LTD
Dagenham

In Convalescence after Influenza, Pleurisy, Pneumonia, Bronchitis

The soothing, inflammation-allaying properties of Angiers Brand Emulsion and its general tonic effects especially commend its use in convalescence from acute respiratory affections. It will clear up any remaining catarrh, whether of the respiratory or digestive organs. It will restore tone to the digestive functions, and greatly improve assimilation and nutrition.

An absolutely perfect emulsion, it is presented in a form pleasing to the taste, and acceptable to the most fastidious. Moreover, it can be administered to advantage in conjunction with other remedies, such as salol, aspirin, bismuth, etc.

'Angiers' is made with petroleum specially purified for internal use. It is the original petroleum emulsion, the result of many years of careful research and experiment.

Haematopoiesis

NEO-HEPATEX

(Parenteral)

Prolonged and world-wide experience of Neo-Hepatex has proved that no other liver product surpasses it in potency.

The combined advantages of high hæmopoietic power and low price render treatment with Neo-Hepatex remarkably economical in cost.

Physicians everywhere are now agreed :—

- (a) That in Liver therapy the variation of requirement in different cases of primary anæmia is so pronounced as to render it impossible to foretell the dosage required with any degree of certainty.
- (b) That whilst a system of dosage based upon minimal quantities may be harmful, there is no danger in over-dosage.

Adequate dosage of Neo-Hepatex, though small in volume, ensures rapid progress with eventually the longest possible intervals between the injections necessary for maintenance.

Neo-Hepatex is issued in ampoules :

Boxes of 6 x 1 cc. 5/-; 6 x 2 cc. 7/ 6; 3 x 4 cc. 6/6

Cystopurin

The ideal urinary antiseptic for oral administration!

- | | | | |
|---|---|---|--|
| 1 | Produces no gastric irritation or toxic symptoms. | 5 | Acts from the renal pelvis downwards. |
| 2 | Is readily absorbed from the gut and excreted in the urine. | 6 | Is active in either acid or alkaline urine. |
| 3 | Causes no renal irritation. | 7 | Perfectly safe for use in febrile conditions. |
| 4 | Renders the urine bactericidal in low concentrations. | 8 | Acts on all causative organisms of urinary infections. |

PYELITIS

From information received:—

"I am glad to inform you that I obtained very encouraging results from Cystopurin in a case of pyelitis of five years' duration. The discharge has greatly decreased and the mild pain of which the patient was complaining entirely subsided after five days' course of treatment."

"I have used Cystopurin in a case of acute pyelitis in a child of 3 with good results. The child could not take Mist. Pot. Cit., but we managed to get crushed tablets down in glucose solution."

"I tried Cystopurin on a case of pyelitis in a girl of 2½. The urine was loaded with pus and there was enuresis and typical swinging chart of septic type rising to 103°.

"At first on a dose of one tablet three times a day there was no change. After 3—4 days I increased to 2 tablets 3 times a day. Fever disappeared and the enuresis improved at once but pus continued. Yesterday no pus seen on sedimentation (i.e. standing over night) for the first time, and is scarcely incontinent now."

"This case (pyelitis) operated in hospital and one kidney removed. When she was able to come back to the surgery the urine was found to be loaded with albumen and pus. After 10 days' treatment (Cystopurin) t.i.d. no pus present, only slight trace albumen. This cleared up after another week's treatment."

Supplied in bulk and in tubes of 20 tablets for dispensing purposes.

Samples and literature available on request to

GENATOSAN LIMITED, Loughborough, Leicestershire.

COCAINE—With 1% cocaine solution, an average of 173 seconds elapse before the touch of a wooden applicator on the eye-lid is no longer felt.

BUTYN—With a 1% solution of Butyn, (Abbott), an average of only 63 seconds elapse before the touch of a wooden applicator is no longer felt.

COCAINE—With 1% cocaine solution the duration of anaesthesia is no longer than that obtained with 1% Butyn solution. Note the dilatation.

BUTYN—With 1% Butyn solution, anaesthesia persists for approximately as long as when 1% cocaine is used. Note absence of dilatation.

RAPID • PROFOUND

Among local anaesthetics—including cocaine—which are effective on intact mucous surfaces, Butyn is unique in its ability to produce rapid, profound and prolonged anaesthesia. Butyn is widely used and is recommended for topical application in operative procedures on the eye, nose and throat, as well as for use in genito-urinary work. • Butyn 2% Solution, the most widely used preparation of the drug, has proved to be as effective clinically as a 5% solution of cocaine. Used in the eye, Butyn does not affect the accommodation nor ocular tension. Neither does it cause drying of the conjunctiva as does cocaine. Two or three drops of the 2% Solution in the eye are sufficient for the removal of impacted foreign bodies or for the relief of pain due to abrasion of the cornea.

For operations, stronger solutions (up to 5%) are employed. • Topical applications of Butyn 2% Solution are sufficient for operations in the nose and for surface anaesthesia in the throat. For genito-urinary use, Butyn gives excellent results even in cases where the mucosa is extremely painful. • Butyn is non-narcotic and is not habit-forming. Its solutions are slightly antiseptic, stable and may be boiled. • Butyn 2% Solution is available in 1-ounce bottles through prescription pharmacies. Butyn is also issued in 3-grain tablets and in powder form. Descriptive literature will be sent on request. The coupon is for your convenience.

Cod Liver Oil

is the Liver Oil with the

**OFFICIAL BACKING OF THE MINISTRY
OF HEALTH AND LEAGUE OF NATIONS
NUTRITION COMMITTEE**

As every practitioner knows, no other liver oil has such a record of achievement as Cod Liver Oil. For it contains Vitamins A and D in the right proportion. In fact, the study of vitamins originated through Cod Liver Oil. Its only drawback in the past has been its taste. Now this difficulty has been overcome. "SevenSeaS" provides, *for the first time*, Cod Liver Oil in a palatable form—so palatable that it can be taken with ordinary foods, and it is available in "High Potency" form, too.

"SevenSeaS" is obtainable in three forms: (1) "High Potency" Oil—four times "B.P." standard; (2) "High Potency" Capsules containing 5 mm. dose of "High Potency" Oil; (3) Standard "B.P." Oil. We would like all practitioners to prove "SevenSeaS" "High Potency" Cod Liver Oil to their own satisfaction. Please send to the address below for a free sample.

SEVEN SEAS
COD LIVER OIL

A new hæmostatic for local application

FER-DE-LANCE VENOM SOLUTION (BOTHROPS ATROX)

Lederle

COAGULATING VENOMS are said to be superior to other agents used as local hæmostatics because they quickly produce a firm fibrin clot, hasten the clot retraction, and do not require collaborating factors such as thrombokinase, calcium, or prothrombin to coagulate the fibrinogen. The venom acts as a thrombin substitute and requires only the presence of fibrinogen to form a clot.

"Fer-de-Lance Venom Solution (Bothrops Atrox) *Lederle*" is a hæmostatic indicated in the treatment of surface bleeding; nasal bleeding; hæmorrhage following tonsillectomy and tooth extractions; bleeding gums in patients with leukemia and purpura hæmorrhagica; hereditary familial telangiectasis; and in surface wounds where there is an abnormality in the coagulating factors, as in hæmophilia.

The hæmostatic action of "Fer-de-Lance Venom Solution *Lederle*" is complementary to that of "Snake Venom Solution (Moccasin) *Lederle*" which is administered by injection and which acts to strengthen fragile vessel walls, but has no specific blood coagulating effect.

Pediatricists

approve these purées

A range of Strained Foods giving maximum nutritive values

THE nutritional value of vegetable purées for infants and soft diet cases is receiving the endorsement of the medical profession to a very marked degree.

Hitherto the difficulties and deficiencies of home preparation—inefficient sieving and destructive oxidation—not to mention the tedium and labour involved—have hindered practical application, but the introduction of a complete range of strained foods by H. J. Heinz Co. Ltd. has been universally accepted as the solution of this problem.

H. J. Heinz Co. Ltd., with their exceptional experience in food preparation, have recognised the legitimate possibilities of supplying strained foods of that maximum nutritive value, uniformity and convenience which only good factory practice can achieve.

The vegetable and fruit purées of H. J. Heinz Co. Ltd. are prepared under conditions of the most scrupulous care with special reference to minimising mechanical loss of mineral salts and other soluble nutriment. The edible portions are washed and trimmed and then cooked under light steam pressure until in perfect disposition for comminution by extrusion and cutting. All mineral salts, vitamins and other soluble nutriment are retained, while harsher fibres, if any, are so reduced as to be non-irritant. The raw materials are purchased when and where seasonal and regional conditions of growth are most favourable, and only fresh gathered vegetables of the highest quality are used.

After the straining process the purée is adjusted to a proper solid content convenient for marketing. Absorbed air is removed and sealing *in vacuo* follows in specially prepared enamel-lined containers. The process concludes with high-temperature sterilisation.

The Lister Institute

OF PREVENTIVE MEDICINE

Therapeutic Substances Act, Licence No. 9

Concentrated Anti-Meningococcus Serum (Group II)

(Globulin Solution)

The serum therapy of infections caused by group II organisms is often less successful than the specific treatment of group I infections due to types 1 and 3, which are usually associated with epidemics of cerebrospinal fever. Accordingly, a group II serum has been specially prepared at the Serum Department of the Lister Institute. This serum has been subjected to a process of concentration so that a large proportion of the inactive proteins has been removed; the dose of antibody is thus contained in a smaller volume of fluid.

Three preparations are issued in concentrated form:

- (1) Anti-meningococcus serum (multivalent)
- (2) Anti-meningococcus serum (Group I)
- (3) Anti-meningococcus serum (Group II)

Anti-meningococcus Serum for Diagnostic Purposes

Particulars with regard to these sera are obtainable from

DO YOU KNOW?

1. A cereal food as rich in protein as cooked beef or cheese? (139 protein calories per 100 gms.)
2. A food which contains only 5 per cent. of moisture as against 76 per cent. in boiled white fish and 66 per cent. in eggs?
3. A food that provides 200 units of Vitamin B₁ for 1d. as against the 200 for 8d. of yeast and the 200 for 1s. 2d. of bran?
4. A cereal food that is pre-eminently suitable for patients on light (even fluid) diet?
5. A food that solves the problem of supplying the 500 to 1,000 International units of Vitamin B₁ needed daily by pregnant women and nursing mothers merely by adding from 1½ to 2½ ounces to their diet?

Bemax supplies the answer to these and many other questions. In the treatment of disease by dietetic methods Bemax commends itself on many grounds:—

1. It is an entirely natural food, without additions of any kind.
2. Its fibre content is very low (1.5 per cent.) and cannot affect even the most delicate tissues.
3. The normal daily dose of Bemax supplies, in addition to Vitamin B₁, significant quantities of Vitamins B₂ and B₆, copper, iron and phosphorus, as well as rich quantities of Vitamin E and other essential dietary elements.
4. It is delightfully palatable and the administration of massive doses of B₁ presents no difficulty on this score.
5. It is by far the most economical method of supplying the diet with Vitamin B₁—the daily spoonful contains from 4 to 10 times as much as the recommended daily dose of certain Vitamin B₁ concentrates advertised to the medical profession.
6. The quantity of Vitamin B₁ supplied by the normal daily dose of Bemax—one tablespoonful—is 200 International units, *an amount sufficient to raise a deficient diet to an optimal level.*

For years it has been the policy of the proprietors of Bemax to ensure its Vitamin B₁ activity by biological assay of every day's output. So far as is known, Bemax is the only food product for which such a claim is or can be made.

BEMAX

A unique natural source of accessory nutritional factors.

Clinical sample and literature on request.

Mapharside

**AN IMPROVED
ARSENICAL FOR
THE TREATMENT
OF SYPHILIS...**

MAPHARSIDE' (meta-amino-para-hydroxy-phenyl-arsine oxide hydrochloride) is a potent spirochæticide which is the result of co-operative research by groups in two American Universities and the Research Department of Parke, Davis & Co. This compound contains 29 per cent. of arsenic and it is effective in a dosage approximately one-tenth that of arsphenamine.

Some Advantages of 'Mapharside'

1. 'Mapharside' is practically a pure chemical substance.
2. 'Mapharside' solutions do not become more toxic on standing.
3. 'Mapharside' is ready for injection by simple solution of the ampoule contents—no neutralization is required.
4. 'Mapharside' permits treatment of syphilis with small doses of arsenic.
5. Reactions following use of 'Mapharside' are apparently less severe than those observed after the use of arsphenamine and neoarsphenamine.
6. 'Mapharside' is chemically and biologically assayed.

Supplied in one-dose ampoules of 0.04 and 0.06 gm.

THE PATHOLOGY OF ADOLESCENT SCOLIOSIS

BY

R. G. ABERCROMBIE, M.D.

Physician for Orthopaedic Diseases, Royal Hospital, Sheffield; Medical Director, Edgar Allen Institute, Sheffield

Adolescent scoliosis is distinguished from other forms of scoliotic curvature by its incidence among young girls, by the special tendency to rotation of vertebrae which accompanies the lateral curves, and by the obscurity which surrounds its causation and pathology. This last feature has given rise to the synonym of "idiopathic scoliosis," in contrast to curvatures associated with recognized pathological conditions, such as congenital malformation of vertebrae, paralysis of spinal muscle-groups, or contractures following intrathoracic disease. Adolescent kyphosis is also of obscure origin; it differs from adolescent scoliosis in that it shows itself at a somewhat later age, it is far more frequent in boys than in girls, and it gives rise to little or no lateral curvature or rotation. Further, in adolescent kyphosis the x-ray examination shows early and striking changes in the vertebrae, fully described by Calvé and Galland (1930); whereas in adolescent scoliosis the x-ray appearances during the early stages are quite normal, the wedging of vertebrae being a late manifestation. Ambiguity has sometimes arisen in the literature owing to the fact that in true adolescent scoliosis there may be a backward or kyphotic element in the dorsal lateral curve; and also that in true adolescent kyphosis there may be a slight and unimportant lateral deviation. There is, however, no clinical difficulty in distinguishing between the two conditions, and there is little doubt that they are pathologically quite distinct. In this paper I confine myself entirely to the question of the causation and pathology of adolescent scoliosis.

Many theories have been put forward to account for a malady so enigmatic in origin and so severe in its results. Perhaps that most widely held is to the effect that the curvatures are a consequence of some form of weakness of the muscles or other structures of the spine. This view has recently been restated by Hauser (1937), who suggests the term "decompensation" for the hypothetical muscular insufficiency. It is difficult to accept weakness as the sole or principal cause, since the condition may show itself in girls who are muscularly vigorous and strong, leading apparently normal and healthy lives, and may advance to severe and permanent deformity without sign of any malady other than that of the curvatures themselves. It is true that the condition is sometimes seen in girls of the "slender maiden" type, who have "shot up" beyond their strength. Such cases are usually mild and postural in type, since the majority of severe cases show themselves prior to the period of rapid growth. In the "slender maiden" type it seems probable that the bodily weakness may be a subsidiary though not the sole

cause of the abnormal posture. Inequality in the length of the legs, unilateral occupations, and defective respiratory movements of one side of the chest have been put forward as causes. Such factors may give rise to an adaptive curvature, but I have not been able to find clinical evidence of their capacity to cause the characteristic symptoms of true adolescent scoliosis, with its secondary curvatures and rotation and its occasional progressive tendency. Analysis of the aetiological factors and of the symptoms has led me to the belief that the posture and deformities are not due to any form of weakness, but, on the contrary, are the result of long-continued abnormal muscular contraction.

Aetiology

Adolescent scoliosis affects girls far more frequently than boys. It shows itself in late childhood and early youth, and is thus associated with the approach or establishment of puberty.

Social Incidence.—Taking my personal experience over a number of years, I believe that adolescent scoliosis is relatively more frequent among the children of the comfortably-off than it is among the hospital class. I have been impressed by its incidence in the sedulously reared only daughters of well-to-do parents. In the hospital class it is the more carefully tended children that are usually affected; among the neglected children of the very poor it is rare. It is thus certainly not a deprivation disease; on the contrary, it appears to be associated with too anxious and solicitous an upbringing.

Recent Incidence.—There has been a massive reduction in the number of cases during recent years. This applies to all social classes and to all institutions in Sheffield and, so far as my inquiries go, to the country generally.

Characters of Curvatures

So gradual is the development of the faulty posture that it is usually impossible to fix the time of its origin; indeed, it is often discovered by chance. At this stage the girl does not complain of pain, fatigue, or any other symptom, and seems unaware of the defect in her attitude. The curvature is known as "postural" or "functional" if the form of the vertebrae is unaffected, so that it is possible to redress the attitude; when deformation of the vertebrae has occurred the attitude cannot be fully redressed, and the curvature is known as "structural" or "organic." In structural curvatures the attitude is often accentuated by a superadded functional element. indi-

WINTER AILMENTS

One teaspoonful of Eno's 'Fruit Salt' is equal in alkalizing value to eight ounces of orange juice.

We all know that sickness is more prevalent during winter than in summer. There is less sunlight and we spend more time in close, overheated rooms. We also take less outdoor exercise just when we should take more. The result is a reduced capacity for resisting disease, and a seasonal wave of increased "physiological unemployment" overtakes us.

There is also another factor. Physical health depends on the maintenance of a uniform constitution in our blood. An almost unmeasurably small variation in its alkalinity causes sickness; whilst a measurable variation causes serious disease, or even death. What is known as acidosis is about the most serious condition to which the body is subject.

In winter time we eat less fruit and green vegetables, and more meat and bread and other heat-yielding but acid-forming foods. What is known as our alkali reserve is thus materially reduced with the result that many of us oscillate between a state of health and half-health.

A daily dose of Eno's 'Fruit Salt' is an effective means of countering the ill-effects of our winter dietary. A series of researches conducted by a well-known bio-chemist has shown that one teaspoonful of ENO is equivalent in alkalizing value to eight ounces of orange juice. Eno is, therefore, the preparation of choice whenever "acidity" is suspected. Eno does not contain sugar, and, therefore, no restrictions need be placed on its general use.

ENO'S 'FRUIT SALT'

The words 'Eno' and 'Fruit Salt' are registered trade marks.

ident bearing should be encouraged by games and sports, and there should be friendly comradeship with the opposite sex.

Summary

The posture and deformity of adolescent scoliosis have an affinity with the attitude of bashfulness. This attitude is the expression of the modesty of puberty; it is defensive in origin, and is dependent on an ancestral postural reflex. In certain cases the modesty of puberty deepens into a morbid self-consciousness associated with an exaggeration of the postural reflex of bashfulness; and the consequent long-continued muscular contraction induces the scoliotic posture and deformity. Recognition of the psychological element increases the scope and effect of treatment.

AN OUTBREAK OF PARATYPHOID AND DYSENTERY IN A TRAINING-SHIP

BY

EDWARD R. PEIRCE, M.R.C.S., L.R.C.P.,
D.P.H., D.T.M.

Senior Assistant Medical Officer of Health, Port of
Liverpool

An outbreak of paratyphoid fever occurred in a Mersey training-ship during September, October, and November, 1937; this was of particular interest in that it happened in a closed community and ran concurrently with a smaller outbreak of Sonne dysentery. The vessel is a third-class cruiser, about fifty years old, used in training boys for the lower deck of the Royal Navy or Merchant Service. The ship's complement consisted of the commander, thirteen officers, and 112 boys; in addition the commander's wife and a maid live in the vessel. A local practitioner is responsible for the medical care of the boys.

On October 5, 1937, the following facts were ascertained by the senior assistant port medical officer:

1. That on September 18 two boys, suffering from pyrexia and malaise, were sent to Birkenhead General Hospital for observation, and were subsequently diagnosed as cases of Sonne dysentery; one of them returned to the vessel on September 29, but was again taken ill, and was readmitted to hospital on October 3 with paratyphoid fever.
2. That on September 19 twelve boys complained of diarrhoea. All recovered in twenty-four hours.
3. That on October 1 one boy, and on October 3 two boys, were removed to Birkenhead General Hospital for observation.
4. That on October 4 the visiting medical practitioner was informed by the bacteriological department of the Birkenhead General Hospital that the patients admitted on October 1 and October 3 were suffering from paratyphoid fever.

On October 5 the medical officer of health for the City and Port of Liverpool received notification of a case of ? paratyphoid fever in the training-ship; the boy was examined by the senior assistant port medical officer and removed to Fazakerley Hospital. Bedding and effects of the patient were collected for disinfection and the ship's hospital washed down and sprayed by an inspector of the Port Health Authority.

General Investigations

The boys returned from summer leave on August 26, 1937, and a number of new boys joined between that date and September 30. The latter group included one (G. R. N.) who will be referred to again later in the report; he joined on September 9, reported sick on September 17 with indefinite symptoms, and remained in the ship's hospital until September 24. The following day he went home on week-end leave and did not return to the vessel, his parents withdrawing him for health reasons. (This boy was subsequently visited at home, and his parents persuaded to allow him to enter hospital.) Except for the aforementioned cases no other sickness was reported.

Water and Food Supplies

Drinking-water is obtained from a hydrant on Rock Ferry Pier four times daily, conveyed to the vessel by water-boat, and pumped into storage tanks on the upper deck. The tanks are used exclusively for drinking-water. River water is utilized for flushing latrines, urinals, and lavatories; there is no possible contamination of the drinking-water from this source. Food supplies are kept in store-rooms used especially for that purpose, and are the direct responsibility of the cook, who has the assistance of four boys in the galley. Milk in bulk is used only for cooking; for drinking purposes each boy receives a pint of pasteurized milk daily in a sealed bottle.

Lavatories, etc.

The lavatory accommodation was inspected; it is situated forward, and consists of trough-closets without partitions. The contents of one large tank flushes the system four times a day; a trough-type urinal is similarly flushed. A separate pedestal water-closet and urinal are available for use at night, but are locked during the day. The hospital has a separate water-closet. As the night urinal opened on the sleeping quarters representation was made that it be completely boarded up, and a new scuttle cut into the ship's side for ventilation; this was carried out at once.

Personal Hygiene

The commander undertook that the crew would adhere strictly to the following instructions:

1. That the boys wash and scrub their hands with hot water and soap immediately after micturition or defaecation.
2. That latrines and urinals be flushed every hour, and seats thoroughly scrubbed each day with disinfectant.
3. That handling of food be restricted to the cook and galley staff (four boys); that no other boys be allowed in the galley.
4. That uncooked vegetables, lettuces, etc., shall not be used.
5. That no new boys shall join the vessel during the present term.
6. That no boys be drafted to sea during the present term.
7. All home week-end leave to be stopped.
8. Football fixtures with other teams to be cancelled, but games ashore permitted among the boys themselves.

Sequence of Cases, and Measures taken after October 5, 1937

October 7.—One of the galley boys reported sick, with pain in the left upper abdomen; temperature 100° F.; he was removed to Fazakerley Hospital for observation. Blood was

cating an influence at work which tends to increase the deformity. Functional cases usually recover with treatment, but occasionally they pass into the structural phase while under observation. If the case is structural when first observed, evidence is lacking as to whether an earlier functional phase has been present. The disputed question as to whether certain cases are structural from the beginning is therefore at present undecided. The various anatomical types of curvature need not here be described.

Explanation of Symptoms

The posture and deformity of adolescent scoliosis are an exaggeration of a physiological attitude, that of bashfulness. On more than one occasion I have known an access of bashfulness during medical examination to be mistaken for a postural scoliosis. At the approach of puberty the girl loses the care-free movements of childhood and becomes modest, self-conscious, and sometimes bashful. Modesty is an instinctive safeguard for immaturity. The bashful attitude is also a defensive one; it depends upon the activity of an ancestral postural reflex, and has the effect of a modest self-effacement which conceals the lineaments of the figure by the sidelong posture and the torsion of the trunk. It is thus in complete contrast to the erect attractive poise of fully developed womanhood.

Natural modesty is physiological, but it may deepen into a morbid self-consciousness, and the associated attitude of bashfulness may then become habitual. In such instances the ancestral postural reflex may assume control, the attitude passing by insensible gradations into the pathological posture of adolescent scoliosis. In unfavourable cases the long-continued muscular contraction may induce structural changes in the young and plastic tissues, and the spinal deformity becomes organic.

In the form of curvature most usually seen the predominant curve and rotation are to the right in the dorsal region, with a subsidiary curve to the left in the lumbar region. The abnormal posture is thus most noticeable in the neighbourhood of the right shoulder. The explanation of the frequency of this particular curve may be that the posture is essentially expressive, and that in expressive gestures it is the right upper limb that is usually called into play. It is the right hand that is waved, the right fist that is clenched, and the instinctive posture of adolescent scoliosis is also to the right. In a left-handed girl suffering from scoliosis the curve was to the left in the dorsal and to the right in the lumbar region.

Rotation is thus to be regarded as part of the attitude brought about by muscular contraction, and not as a mere concomitant of the lateral curves, to which it is often quite disproportionate in grade. Rotation is a far more noticeable feature in adolescent scoliosis than in other types of lateral curvature, in which it is a concomitant. A very different pathological condition serves to illustrate the origin of spinal curvatures in long-continued postural muscular contractions. The morbid changes of encephalitis lethargica sometimes lead to the release of ancestral postural reflexes in a perverted form. The bizarre attitudes which result may give rise in young subjects to structural spinal deformities (Abercrombie, 1928).

Significance of the Aetiological Factors

The import of the incidence among young girls has been discussed. Typical adolescent scoliosis is also occasionally seen in boys. At a stage in their development boys sometimes show well-marked feminine characteristics and become as modest and as bashful as a girl, and are thus

also open to the train of pathological events which have been described. The disproportionate incidence among more carefully nurtured children suggests that too anxious a solicitude in upbringing may impair self-reliance and induce a morbid self-consciousness. Several writers have noticed an abnormal psychological state associated with scoliosis. It is not easy to define. The girls are not hysterics; the disturbance is at the level of instinctive behaviour, and the defect is not so much in the personality as in its environment.

The diminished incidence in recent years corresponds to a more rational system of education, with its games and open-air sports. The results are to be seen in an upright carriage and a demeanour at once modest and self-reliant. In former days false modesty seems sometimes to have been taught as part of the curriculum. A manual of conduct published in 1871 recommends "a pleasing modest reserve and retiring delicacy that blushing withdraws from the gaze of admiration." It is interesting to recall that this was the period of the routine use of the back-board.

Instances occur, although they are rare, in which the symptoms of adolescent scoliosis show themselves after an acute infection. The interpretation appears to be that during a critical stage of a girl's development the debility of convalescence may affect her mentality, rendering her timid and self-conscious. This mental change in association with the bodily weakness may induce scoliosis. In one case severe adolescent scoliosis followed directly upon an attack of acute chorea.

Treatment

Although it is difficult to estimate the results I believe that the recognition of the psychological element in adolescent scoliosis increases the efficiency of treatment, and it certainly adds greatly to its interest. The relatives should be instructed that the anxiety which they so often show is unwholesome for the patient, and they should be forbidden to worry her about her attitude. Treatment should be directed to both mind and body. Psychological treatment should be indirect. The girl should be placed in a healthy and cheerful moral atmosphere. The less said about the curvature the better. In the treatment of postural curvatures in my judgment it is best to disregard the individual curves altogether and to rely on free-standing exercises under a judicious and trained instructress. The object of the exercises is to give confidence and to improve the bodily poise, and it is essential that they should be enjoyable.

Structural curvatures are a more difficult problem. Much ingenuity has been employed in the design of exercises to correct special curves and to strengthen special muscle-groups. However skilfully carried out, the results are disappointing. I incline to the view that in place of this highly specialized treatment equally good results are obtained by general exercises of an invigorating and enjoyable character designed to improve the bodily poise. With some diffidence I record the impression that the condition may be sometimes actually aggravated by too intense an attention directed to particular curves. In overgrown girls it is reasonable to order a daily period of dorsal recumbency. It is outside the scope of this paper to discuss the treatment of severe structural curvatures by means of forcible reduction, fixed apparatus, or surgical operation.

A few words may be added with regard to prevention. Parental solicitude should not be allowed to interfere with the development of self-reliance. A free and con-

		Later Report								

taken for Widal test from twenty boys who gave a history of pyrexia and/or diarrhoea since August 26. Specimens of faeces and urine from the cook and four galley boys were forwarded to the City bacteriologist.

October 11.—Two boys with pyrexia removed to Fazakerley Hospital for observation. Blood for Widal test taken from the cook and galley staff.

October 12.—Eight boys with pyrexia and/or diarrhoea removed to Fazakerley Hospital for observation. Arrangements made for a daily "temperature parade" of all boys in the ship, and the results reported to the senior assistant port medical officer. All febrile cases, irrespective of symptoms, were drafted to hospital for observation.

October 13 to October 20.—Nineteen boys were segregated during this period.

October 18.—Blood was taken from the six remaining new boys who joined the vessel on or after August 26. Arrangements were completed for the routine examination of faeces from all aboard, and six specimens were submitted daily to the City bacteriologist.

October 31 and November 6.—Three boys on the former and one boy on the latter date were removed to Fazakerley Hospital.

November 8.—Two boys were readmitted to Fazakerley Hospital suffering from severe diarrhoea.

November 12.—A dysentery carrier was isolated from the routine examination of stools and removed to Fazakerley Hospital.

The question of preventive inoculation with T.A.B. was considered, but was rejected on account of the danger of masking future cases and the absence of evidence as to the advantage of such inoculation during the course of an epidemic. It was, however, deemed expedient to obtain permission of parents and guardians for the inoculation of boys should the contingency arise. This was obtained in all cases except those under the care of one voluntary society, which refused.

The total number of admissions to hospital for observation was forty-four (including three readmissions), and the following results were obtained:

Dysentery group	5

Investigation and Progress of the Epidemic

The investigation of this epidemic was complicated by the presence of both paratyphoid B and Sonne dysentery; the fact that it was confined to a closed community where strict discipline could be maintained was of material assistance.

Dysentery Cases

A scrutiny of the bacteriological reports (Table I) reveals the isolation of *B. dysenteriae* Sonne from one patient (S. C.) who had no previous symptoms. This boy joined the vessel on July 14, 1937, and the dysentery epidemic began on September 18, when two boys (J. V. and R. W.) were sent to Birkenhead General Hospital. Next day twelve boys complained of diarrhoea, which cleared up in twenty-four hours. These facts were first reported to the Port Health Authority on October 5, following which a routine examination of faeces was instituted. From these examinations a positive return (S. C.) was made on November 9; the boy was removed to hospital, and since his segregation no further cases have occurred. In attacks of mild diarrhoea in two other cases the organism was isolated from the faeces; these patients were admitted to

Fazakerley Hospital, one (W. G.) on September 11 and the other (K. C.) on September 12.

One case (J. V.) was of particular interest. This patient was discharged from Birkenhead General Hospital on September 28 and readmitted on October 3 with paratyphoid fever; he would therefore seem to have incubated paratyphoid during the course of his dysentery.

Paratyphoid Cases

The Liverpool Port Medical Officer was first notified of paratyphoid fever in the training-ship on October 5, and investigations were proceeded with to find the source of infection. Attention was directed to the water supply, food supply, galley staff, and the possibility of a carrier or missed case.

Water Supply

The storage tanks on the forecastle head and main deck were examined and samples taken by an assistant to the City bacteriologists, with the following results:

	Bacteria per c.cm. at 37° C.	Bacteria per c.cm. at 22° C.	<i>B. coli</i> absent in
Tank, main deck .. 3	114	100 c.cm.	
Tank, forecastle .. 5	143	100 c.cm.	

No organisms of the typhoid group were found in either specimen. After due investigation it was considered improbable that the water supply was the origin of the infection.

Food Supply and Galley Staff

Particular attention was directed to milk and uncooked vegetables, but it was considered unlikely that food was the origin of the outbreak. Samples of blood, urine, and faeces from the cook and four galley boys were submitted to the City bacteriologist. One of these boys (J. L.) was removed to Fazakerley Hospital on October 9 with paratyphoid fever. The blood Widal reaction was positive, and *B. paratyphosus* B was isolated from the faeces and urine. The results from the others were negative.

Carrier or Missed Case

It has already been noted that the boys returned from leave on August 26, and it was ascertained that none of them gave a history of any illness during the vacation. As a number of new boys had joined the vessel between August 26 and September 30 particular attention was directed to this group, and their individual medical histories were investigated. Among them was a boy (G. R. N.) who joined the vessel on September 9; eight days later (September 17) he was sent to the ship's hospital with indefinite symptoms, remaining there until September 24. The following day he returned home on weekend leave, but did not return to the vessel, his parents withdrawing him for health reasons. He was visited at home, and ultimately his parents consented to his removal to hospital. He was admitted to Fazakerley Hospital on October 13, and the next day *B. paratyphosus* B was isolated from the urine; the blood and faeces were negative. On two later dates (see Table I, G. R. N.) *B. paratyphosus* B was again isolated from the urine; both the blood and faeces still remained negative. He was discharged from hospital on November 15; but although at all times the blood Widal was negative and *B. paratyphosus* B was not isolated from the faeces, the fact that the urine was positive on three separate occasions and also that he was a new boy in the vessel seems to indicate that he was the origin of the outbreak.

A urinary carrier with a consistently negative Widal reaction is very rare, but a similar case has been reported by V. Glass and H. D. Wright (*J. Path. Bact.*, 45, 438);

Oct. 31 (C. E. W.)							
(C)							
Nov. 8 (D. E. D.)							

had the organism been isolated on one occasion only, suspicion would naturally have fallen on the technique employed in collecting the specimen, but it would appear more than unlikely that the specimens of urine from this particular patient could be contaminated accidentally on three different dates. On October 1—that is, fourteen days after this boy first entered the ship's hospital—a case of paratyphoid was removed to Birkenhead General Hospital.

Table II shows the incidence of the paratyphoid cases, including doubtful ones, and it will be observed that, assuming G. R. N. to be the origin of the epidemic, a group of five cases occurred between October 1 and October 7; another group of seven cases between October 11 and October 13; one doubtful case on October 31; and the last one on November 8. This seems to indicate that the removal of the original source of infection, plus the rigid carrying out of the personal hygiene instructions, was successful in cutting short the outbreak. In addition twenty-four boys who at the daily "temperature parade" had shown a rise were sent to hospital for observation; repeated examinations of blood, faeces, and urine of this last group were negative. The type of infection was not severe; there were no deaths; one patient was seriously ill but subsequently recovered; the remainder had an uneventful convalescence.

Summary

1. This is the record of an outbreak of intestinal infection in a training-ship, due to *B. paratyphosus* B and *B. dysenteriae* Sonne.

2. The first case of illness was that of a new boy, shown to be a urinary carrier of *B. paratyphosus* B; although blood and faeces were negative the organism was isolated from the urine on three separate occasions. A similar case is reported by V. Glass and H. D. Wright.

3. Of a total complement of 128, eleven boys were definitely paratyphoid and four doubtful; two of the latter had positive Widal reactions, but *B. paratyphosus* B was not found; the blood Widal in the others were negative, and *B. paratyphosus* B was isolated from only one specimen in each case.

4. Mass inoculation with T.A.B. vaccine was considered but decided against. Preventive inoculation of new boys has been advised.

5. Routine examination of faeces revealed a Sonne dysentery carrier as a possible cause of the dysentery outbreak. The organism was isolated in four other cases which showed dysenteric symptoms.

6. Instructions in personal hygiene were issued and stressed early in the epidemic.

7. It was decided to reconstruct the entire lavatory accommodation on modern lines before the end of Christmas leave.

8. Bacteriological investigation of faeces from the personnel has been completed and the epidemic is presumed to be over.

I wish to express my thanks to Dr. W. M. Frazer, medical officer of health to the City and Port of Liverpool, for permission to publish this report.

cannot yet be stated (Walters, personal communication) whether the size of the coronary vein can determine the site of venous obstruction, though it is likely that the size of this vein at operation will be a guide as to whether there is enough venous block in the liver to produce oesophageal piles. There is no need to discuss here the possibility of superior vena cava block causing varices; but it must be clear that once the veins in the lower end of the oesophagus become distended they are columns of blood in direct connexion with the superior vena cava and unprotected by valves.

Operation for Relief of "Splenic Anaemia"

With these details of the vascular mechanisms in mind it is possible to examine the various operative methods of relieving "splenic anaemia." An example of the effect of splenectomy on a patient who had shown previous haematemesis is seen in Case 1. The effect of ligation of the coronary vein has already been dealt with. Warner (1929-30) has reported the result of tying the splenic veins in a boy with "Banti's disease" showing a large liver and ascites. The rationale was to lessen the blood flow through the spleen, and there was a marked immediate improvement. Splenectomy was subsequently necessary, and the patient has been well for the last five years (Warner, personal communication). Ligation of the splenic pedicle has been suggested by McNee (1931), by Graham Bryce (1932), and by Howel Evans (1936). Watson (1935) has reported a successful instance of this operation very similar to Case 2. The patient was a woman, the usual criteria of "splenic anaemia" were present, and she had reached the stage of ascites. Because of adhesions splenectomy was not feasible and the whole pedicle was tied. The spleen became very tender and there was a post-operative thrombosis, but ultimately recovery was complete. Three years later there were no symptoms. The blood picture being slightly subnormal in all respects—as in Case 2—Case 3 is presented as another example of the results of pedicle ligation.

Case 1

A furnace-man, aged 32, was admitted under the care of Dr. A. Douglas Bigland in October, 1935. There was no familial splenomegaly and no residence abroad, and the only previous illness was typhoid fever at the age of 15. There had been a haematemesis six years before, another three years before, and one just before admission. A sallow pallor had slowly appeared, and there had been some symptoms of anaemia. The spleen was found to be one fingerbreadth below the costal margin with no hepatomegaly or ascites. No free hydrochloric acid was produced by a gruel test meal. The barium meal showed no gastro-intestinal abnormality. Dr. Howel Evans reported the blood picture to be: red cells, 3,400,000 per c.mm.; haemoglobin, 35 per cent.; leucocytes, 1,125 per c.mm.; platelets, 122,000; and halometer reading, 7.17 microns. The bleeding and clotting times were unchanged, the fragility normal, and the serum Wassermann negative. By means of large doses of iron for two months the haemoglobin was raised to 80 per cent. and the red cells to 5,000,000. Since several platelet counts showed a consistent reading in the neighbourhood of 100,000 splenectomy was decided on and was carried out by Mr. Hugh Reid. Section of the spleen showed the "diffuse fibrosis usually associated with Banti's disease." In the post-operative period the platelet count did not rise above 700,000 per c.mm. and no thromboses occurred. The patient returned to work soon afterwards and remained well even without iron.

For follow-up purposes he was seen ten months later; he felt very well, was working, and there had been no recurrence of bleeding. The haemoglobin was 100 per cent., the red cells 5,600,000 per c.mm., the leucocytes 12,800 per c.mm., with slight lymphocytosis, reticulocytes 1.5 per cent., and halometer

reading again 7.17 microns. The platelet counts were 165,000 and 186,000 per c.mm. on successive days. On giving a gruel test meal there was again no free acid secreted, but a moderate amount appeared after histamine. Search for oesophageal varices, which was not specially made prior to the operation, showed these to be present and distended sufficiently to be easily recognized by a barium swallow.

Case 2

This patient, a boy of 14 who has for many years been under the care of Mr. J. T. Morrison, to whom I am indebted for permission to publish the case, is an only son and first cousin to Case 3. There was no other instance of splenomegaly or anaemia in the family, and those of his relatives I was able to examine were all normal. From 1929 to 1931 he was in hospital most of the time with the sequelae of an appendix abscess and empyema. There was then no splenomegaly, and two blood counts showed a secondary anaemia and leucocytosis. From 1932 to 1935 there were four haematemeses, and he was in hospital several times. Clinically there was anaemia, some stunting of growth, and a spleen enlarged to an inch below the costal margin. A typical blood count was: red cells, 3,300,000 per c.mm.; haemoglobin, 45 per cent.; leucocytes, 2,500 per c.mm.; and platelets, 137,500 per c.mm. The serum Wassermann was negative, as were those of his parents; the bleeding and clotting times and the blood fragility were within the normal ranges. Operation was refused until 1935, by which time ascites had appeared. When the abdomen was opened the spleen was found to be so adherent that removal would have been impossible. Mr. Morrison therefore tied the splenic pedicle vessels. Recovery from operation was rapid, and the boy gained his proper weight and height. Within a few months he was able to play games for the first time for several years.

I examined him two years later. He was then a well-grown boy, but the olive tint of the face persisted. The rounded splenic edge could be felt on inspiration. The gruel test meal revealed small amounts of free acid. The blood picture (no iron had been given since the operation) showed: red cells, 4,624,000 per c.mm.; haemoglobin, 95 per cent.; leucocytes, 5,680 per c.mm.; reticulocytes, 1.5 per cent.; and platelets, 190,000 per c.mm. The fragility was unaltered. The radiologist was able to show well-filled oesophageal varices.

Recently, after four days of sore throat and pain on swallowing, another large haematemesis occurred, following which the spleen shrank so as to be almost impalpable. The liver was not enlarged, and there was no ascites or other evidence of portal cirrhosis. The oesophageal veins were again seen radiographically. Here once more the dangers to which the varices are exposed—perhaps this time there was an oesophagitis—were emphasized.

Case 3

A married woman, aged 24, was admitted to the Liverpool Royal Infirmary in September, 1936, under the care of Dr. Bigland. She had never been abroad and had had no previous illness of note. Despite this she had always been pale and tired. During the last five years there had been frequent dyspepsia, and food seemed to stick at the level of the lower end of the sternum, and for the last year she had suffered from dyspnoea and substernal effort distress, possibly due to the anaemia. Just before admission she had vomited about two pints of blood. The facies was olive-tinted, the heart showed a basal haemic bruit, and a firm-notched spleen reached to the umbilicus. Dr. Howel Evans reported the blood picture as: red cells, 4,260,000 per c.mm.; haemoglobin, 50 per cent.; leucocytes, 2,250 per c.mm.; platelets, 136,000 per c.mm.; with pallor but no microcytosis of the red cells. The serum Wassermann was negative, and the clotting time, bleeding time, and fragility were within the usual limits. The stomach tube could not be swallowed, but the barium meal showed no gastric abnormality. Extensive oesophageal varices were present. For the next three months the patient was

RECURRENT HAEMATEMESIS IN "BANTI'S DISEASE"

BY

ROBERT KEMP, M.D., M.R.C.P.

Registrar, Liverpool Royal Infirmary

The physician who discusses the splenic anaemia syndrome finds himself in an uneasy and apologetic position. This is of course because the pathologist is able to make the statement that primary Banti's disease does not exist. But at the bedside the use of the term must be conceded to cover those instances of splenomegalic anaemia for which none of the many known causes can be found. This position is supported by Whipple's (1937) record of a group of thirty-one patients with "Banti's disease." In no fewer than fifteen of these it was not possible to find the causal factor. So that, as Castle and Minot (1936) put it, the problem posed by Banti still remains unanswered. There are three usual explanations employed "to empty the Banti pigeon-hole"—cirrhosis of the liver, obstruction of the splenic vein, and hepato-splenic fibrosis. It is generally held that sections of these spleens reveal changes resulting from long-standing congestion. Whipple uses the term "portal hypertension," and notes that work in his clinic shows that a very high pressure occurs in the splenic vein; and the recollection of the tense bulging splenic veins seen at operation supports this. So that the present attack on Banti's disease is on the vascular and mechanical fronts. But before opening the question of haematemesis I would like to make a few more general points.

In the Liverpool Royal Infirmary records over the last ten years it has only been possible to find twenty cases where there was enough positive and negative evidence to fill the classical criteria. The main facts are embodied in Table I.

TABLE I.—*Twenty Cases of "Splenic Anaemia" at the Liverpool Royal Infirmary (12 men, 8 women; average age, 32.7 years)*

Average Blood Picture:

Haemoglobin, 48 per cent.; red cells, 3,500,000 per c.mm.; white cells, 4,200 per c.mm.; lymphocytic trend.

Platelet Counts:

Thrombocythaemic, 2 cases; normal limits, 2 cases; thrombopenic, 15 cases; no counts, 1 case. Average count in thrombopenic cases, 100,000 per c.mm.

Fractional Test Meals (12 Cases):

Low normal, 4; almost achlorhydria, 1 case; achlorhydria, 7 cases.

Haematemesis occurred in 9 and splenectomy was performed in 7 cases.

It would probably be agreed that the blood picture shown there is the one commonly found. Yet it must be emphasized that such haematological evidence is a shaky diagnostic basis. The red cells and the haemoglobin can be restored to normal by administering massive doses of iron (Davidson, 1934). This must be related to the frequent achlorhydria seen in these cases and those in the literature; though it is not known whether the achlorhydria is histamine-fast. The link between the splenomegaly and the absence of acid is still missing, as is the reason why both the giving of iron and the removal of the spleen correct the anaemia. The leucopenia almost always present in "splenic anaemia" occurs in other splenomegalies and is not diagnostically specific. The platelet count is seen to be low in most cases, but it must be remembered that recent haematemesis will cause an increase to normal

figures: the existence of occasional normal and high counts is again an unreliable diagnostic criterion. The dangers of splenectomy in other than thrombopenic cases have been conclusively shown by Rosenthal (1925) and confirmed by Howel Evans (1928). But with these views Whipple (1937) has expressed disagreement. Because of the relationship of two of the patients cited in this paper an attempt was made to find recorded instances of "familial splenic anaemia," but without success. It was possible to examine six members of this family, but there was no other splenomegaly or anaemia. The only abnormality in the examination and investigation of these people was a persistent thrombopenia in the father of Case 3. Negative though this evidence is, the occurrence in first cousins is probably more than a coincidence.

Splenectomy and Haematemesis

Single or repeated haematemesis is of course a well-known feature of the splenic anaemia syndrome, but it is not so well known that splenectomy does not always remove the liability to this type of bleeding. It had been thought that once the patient had survived the immediate post-operative dangers, the later risk of thrombosis, and the possibility of hepatic cirrhosis he was out of the wood. But most clinicians have had an experience similar to that which aroused my own interest—the rapid and fatal exsanguination of a man apparently doing very well two years after splenectomy. Pemberton (1931) puts this into figures when he records that this symptom recurred post-operatively in 50 per cent. of a group of ninety-eight patients with "splenic anaemia" who bled before the operation. Death was a result of this haemorrhage in twenty-nine patients, against nine from thrombosis and four from hepatic cirrhosis in the larger group of 182 cases of "splenic anaemia." Similarly Dr. Howel Evans, who has followed a smaller series, has seen recurrence after operation in about half the patients and death in several. But it is important to note that only those who bled before removal of the spleen bled afterwards. That these further bleedings are due to growth of the hepatic obstruction is an obvious solution. If we study the figures supplied by Whipple (1937) we will see that much of the recurrent haematemesis is found in the group with hepatic cirrhosis. But I would suggest that though this explanation is obvious it is not the only factor at work. If it were we should have to issue automatically a bad prognosis in these recurrences, and so overlook the patients in whom, as I hope to show, the problem is a simple mechanical one.

If a mouthful of rather stiff barium paste is allowed to slip down the oesophagus of patients who have vomited blood either because of cirrhosis of the liver or "splenic anaemia," the distended oesophageal varices can be outlined radiographically. Kirklin and Moersch (1931) in reporting this confirmed the varices by oesophagoscopy. These veins may extend throughout the lower two-thirds of the gullet; they are large, tense, and immediately submucous. A liability to bleed is obvious, though there may occasionally be another danger spot in distended gastric veins. Kegaries (1934) has shown that the venous bed at the lower end of the oesophagus has three connexions: directly from the portal system via the coronary vein along the lesser curvature of the stomach; indirectly from the splenic pedicle by the vasa brevia; and to the superior vena cava via the azygos veins. In hepatic cirrhosis, then, there will be dilatation of all the veins in the portal system. And the liver will be "by-passed" by a distended coronary vein to oesophageal varices. In "splenic anaemia" without cirrhosis of the liver the venous congestion in the splenic bed will cause the vasa brevia to open up and varices will be formed by the second mechanism. The coronary vein has been tied with good results—as regards haematemesis—when dilated and without result when of normal size (Rowntree, Walter, and McIndoe, 1929). But it

THE ASSOCIATION OF TRAUMA WITH PROGRESSIVE MUSCULAR ATROPHY

BY

G. E. FREDERICK SUTTON, M.D., M.R.C.P.

Honorary Assistant Physician, Bristol Royal Infirmary;
 Lecturer in Clinical Medicine, University of Bristol

We know little indeed about the aetiology of progressive muscular atrophy, but its association with trauma in a small percentage of cases has been described by eminent Continental neurologists during the past decade. Thus Alajouanine, Gopcevitch, and Meillaud (1930) gave an account of an interesting case of post-traumatic muscular atrophy, with an illuminating discussion, on the subject. These authors divide such atrophies into different groups.

The Muscular Atrophy Groups

In the first group the muscular atrophy is localized to the region of the muscles in the neighbourhood of the injured joint. They state that to this group belong some of the amyotrophies of the periscapular region which may follow injuries to the shoulder-joint, and suggest that such amyotrophy is of reflex origin, as is indicated by the electrical changes and by the fact that after progressing for several months cases remain stationary or even regress. They define this type as "localized post-traumatic reflex amyotrophy."

In the second group the amyotrophy ensues rapidly upon the injury, and it develops on a paralytic background. Its distribution is generally radicular, and it is accompanied by sensory changes of a dissociated character which suggest that this type may follow minor traumatic fissures of the spinal cord, with resulting frustrated haematomyelia. In such cases the wasting, at first progressive, becomes stationary after a time. They describe it as spinal amyotrophy secondary to frustrated haematomyelia.

In a third group of cases the wasting develops more slowly. It has not been preceded by any notable paralytic phenomena and is not associated with sensory troubles or reflex abnormalities. The atrophy in such cases may be localized or diffuse and non-systematized. The electrical reactions are not myopathic in type, but conform closely to the changes found in the myopathies. This group progresses for a time, but may later display a tendency to regression.

Descriptive Cases

Alajouanine and his colleagues describe the case of a man, aged 34, who was seen at the Salpêtrière for a diffuse muscular atrophy which had slowly progressed over a period of twelve years. The condition had begun two months after an aeroplane accident which had rendered him unconscious, and in addition to contusions had resulted in a split fracture of the head of the radius.

Another case of post-traumatic muscular atrophy is described by Horst Geyer (1934). This patient sustained a fractured tibia and fibula of the right leg in 1905. Four years later wasting was observed in the right thigh. Clubbing of the right foot was also present as a result of acute anterior poliomyelitis which had occurred in infancy. When examined by Horst Geyer in 1932, in addition to the typical claw hands, wasting and fibrillary tremors were widespread. The ankle and knee reflexes were practically absent, and there was no evidence of any pyramidal tract lesion. The small muscles of the hands and feet showed no response to galvanism or faradism.

The next case described by Horst Geyer is that of a male, aged 52, who in 1921 was struck in the small of the back by a branch of a tree. As a result of this he was unable to work for several weeks, but subsequently recovered. Eight years later he fractured his left leg in a motor-cycle accident. When examined at the clinic on May 9, 1930, the left leg showed marked generalized wasting. No abnormalities were observed in the rest of the body. When seen again three years later there were definite signs of progressive muscular atrophy, wasting and fibrillary tremors being present in all the limbs, though they were more marked on the left side than on the right.

Predisposing Factors

Geyer remarks that these two cases of his have in common the onset of progressive muscular atrophy some years after the original injury. In discussing the frequency and pathogenesis of the condition, he says that of the twenty-one cases which appeared at the clinic between the years 1919 and 1933 only one could be shown clearly to be due to trauma. He quotes Kure, who stated in 1931 that the innervation of muscles is fourfold—cerebral, spinal, sympathetic, and parasympathetic—and disturbance of any of these can lead to muscular atrophy. He points out, further, that many eminent neurologists are of the opinion that the main feature is a congenital predisposition, and that trauma has merely "pulled the trigger" in such cases. This theory, he says, is held by Strümpell, Probst, Oppenheim, and others. Marburg asserts that this is merely a possible theory, and that there is no anatomical evidence in support of it. Other authors maintain that one has to consider the question of an acquired disposition. Rose divides the predisposing factors into five groups: one is the simple type previously mentioned; the other four are acquired—namely, toxic; infective; those occurring after cerebrospinal diseases, such as anterior poliomyelitis; and, finally, the traumatic group, such as those associated with fractures. Other authors also stress the association with anterior poliomyelitis in some cases. Thiern considers that there occurs in the traumatic cases a traumatic neuritis which spreads up towards the spinal cord, and eventually by association with the anterior horn cells produces progressive muscular atrophy. Another theory propounded is that, acting on the congenital or acquired predisposition, there occurs in the traumatic cases a shaking or

treated with large doses of iron and weekly injections of liver extract. The details of the various blood counts are shown in Table II (personal observations). It was clear that the case was thrombopenic in type and suitable for splenectomy. The patient, however, preferred the simpler operation of ligation of the splenic pedicle, such as had been so successful with her cousin. Since it seemed to us that this procedure could do no harm ligation was deliberately undertaken. Mr. Hugh Reid opened the abdomen and found the liver macroscopically

TABLE II.—Serial Blood Counts in Case 3

Date	Red Cells (millions)	Leucocytes (per c.mm.)	Platelets (per c.mm.)
9/9/36	Haematemesis—two pints		
10/9/36	4.24	3,200	170,000
11/9/36	4.00	5,900	222,000
14/9/36	4.16	3,200	91,000
16/9/36	3.68	4,000	81,000
18/9/36	4.08	2,800	53,000
21/9/36	4.16	4,000	65,000
23/9/36	4.00	3,200	63,000
25/9/36	4.26	2,250	136,000
28/9/36	4.32	2,800	96,000
1/10/36	3.20	5,600	106,000
	Out-patient—liver and iron		
6/12/36	5.40	5,660	168,000
8/12/36	5.20	—	161,000
9/12/36	5.20	4,750	98,000
16/12/36	5.12	6,520	94,000
17/12/36	Operation		
18/12/36	5.30	16,000	200,000
19/12/36	5.36	16,000	200,000
20/12/36	5.44	14,600	367,000
21/12/36	5.60	9,600	523,000
22/12/36	5.40	—	745,000
23/12/36	4.80	11,500	300,000
24/12/36	5.04	—	504,000
25/12/36	5.20	6,200	196,000
29/12/36	4.80	—	216,000
30/12/36	5.20	—	400,000
31/12/36	4.64	—	—
1/1/37	4.16	12,800	249,000
2/1/37	4.20	11,200	550,000
3/1/37	4.24	—	424,000
5/1/37	4.96	—	291,000
7/1/37	4.70	—	450,000
9/1/37	Discharge. Convalescence with iron		
19/4/37	5.16 (Hb, 85%)	4,800	129,000
1/5/37	5.90 (Hb, 95%)	8,000	147,000

normal, the coronary vein not dilated, but the vasa brevia larger than usual. The splenic artery was tied in two places and the three splenic veins, each as large as one's thumb, were occluded. The post-operative period was stormy, and a good deal of pain arose from the tender spleen. Convalescence was slow, but four months after the operation the patient was able to get about, though pale and suffering from lassitude. The spleen, while considerably shrunken, was still two inches below the costal margin. Though the red cells were over 5,000,000 per c.mm. the haemoglobin was only 85 per cent., and leucopenia and thrombocytopenia were still present. The radiologist was able to show that the varices

in the oesophagus were unaltered. Intensive iron therapy was prescribed, and slow improvement is taking place.

In addition to these three cases it was possible to examine radiologically two other patients who had been subjected to splenectomy for classical "Banti's disease." In a young man who had had haematemesis both before and since operation there were extensive varices throughout the lower two-thirds of the oesophagus. In a middle-aged woman, in whom there had been no bleeding but in whom hepatic cirrhosis had been found at operation, no varices were to be seen.

The results of pedicle ligation will be of interest to those who advocate the operation. The general effect in Case 2 can be described as excellent, since the lad has grown to his proper height and weight and is able to follow a normal life. Locally the spleen has shrunk remarkably and cirrhosis of the liver has not appeared. Yet his life is hazarded by a problem in vascular mechanics. In Case 3, where the ligation was more deliberately carried out, the result was not so good, but further improvement may be seen. Though the red cells and haemoglobin are kept at healthy levels with the use of iron, there are still many general symptoms. The spleen has been reduced, but it is even now too big to be regarded as inactive. The varices, and therefore the risk of further haematemesis, seem unaltered. There was a good deal of post-operative pain and reaction, as would be expected with such a drastic interference with the blood supply. To counterbalance this there is probably a lower immediate risk, and certainly from the low platelet rise much less danger of thrombosis. But on the whole the patient would have been better off with splenectomy, and may even yet need it. From this small experience one might suggest that ligation of the pedicle may be useful in two situations: where the platelet level is normal or high and splenectomy is likely to be followed by a thrombocythaemia of over 1,000,000 per c.mm.; and at those laparotomies where the adhesions are too thick for safe splenectomy.

It becomes clear, then, that the post-operative study of this type of patient shows that whether the dilated veins at the cardia are formed either from portal obstruction or from a more local obstruction they persist after splenectomy and pedicle ligation. The fact that half the individuals with previous haematemesis do not bleed again is probably due to lessening or stoppage of the blood flow upwards through the vasa brevia. That the other half do bleed again is due to the direct communication between the varices and the superior vena cava. Portal obstruction is therefore not essential to maintain the distension. No doubt the bigger the veins are before operation the more likelihood there is of subsequent haemorrhage. It is a fair analogy to point out that cure of varicose veins in the leg is not attained by distal ligation. The proximal ligation or removal of oesophageal varices is a matter of great technical difficulty and beyond my province. Walfers and Kegaries (1933) have suggested the submucous injection of sclerosing solutions. But one may conclude that in those instances where haematemesis follows splenectomy, and haemorrhage, not cirrhosis of the liver, is likely to be the cause of death, the purely mechanical problem of dealing with the varices will have to be faced.

Summary

It has been shown that, because of the persistence of oesophageal varices after operation in cases of "Banti's disease," neither splenectomy nor splenic pedicle ligation will prevent recurrence of haematemesis.

2. The wasting of muscle is frequently not manifest until many years have elapsed since the original injury.
3. The problem of the way in which the atrophy is brought about is discussed.
4. From the medico-legal point of view alone the subject is of very great importance.

I am indebted to Dr. M. E. Disney, medical registrar, for assistance with the case notes at the Bristol Royal Infirmary.

AETIOLOGY OF ACUTE APPENDICITIS*

BY

A. M. SPENCER, M.B., B.Sc., M.R.C.S.

I. The History of Acute Appendicitis

Although appendicitis is usually regarded as a disease of modern civilization a small number of Egyptian mummies have been found to possess unmistakable signs of chronic inflammation of the organ, and in one case, that of a young royal princess, an acutely inflamed and perforated appendix was beautifully preserved.

The first recorded case in modern Europe was in a patient of Mestiver (Germany) in 1759, but the disease does not appear to have been recognized in England until 1812, when Parkinson diagnosed it in London. For some years the aetiology was obscured by the use of the term perityphlitis; but after 1820 appendicitis was increasingly recognized. Between 1820 and 1840 there were thirty-three recorded cases, and during the twenty years 1840-60 the number had risen to 102. In 1918 the deaths from the disease totalled 2,416. The figures showing the incidence of the disease at the Bristol Royal Infirmary are of interest. In 1880 out of 2,591 patients there were four cases of appendicitis. By 1905 the proportion had risen to sixty-four cases out of 3,762 patients, and by 1918 it had reached 113 appendicectomies in 4,021 patients.

DISTRIBUTION OF THE DISEASE IN THE COMMUNITY

Both sexes are equally prone to the disease, and the age of greatest liability is from 10 to 30 years. While it does occur in infants it is rare to find the disease before 3 years of age. It is also rare to find it at the other extreme of life, but it has been known to occur at 84 years. The disease is more serious at the extremes of life than it is during the years of its maximum incidence. As regards the influence of social position, the disease is definitely more common among the well-to-do; poorer people, especially those living in institutions, enjoy a relative immunity. For instance, there was only one case in ten years at Portland Prison. At Clifton College, Bristol, twenty cases occurred among 500 boys in five years, while at Müller's Orphanage, also in Bristol, there were only four cases among 950 children in the same period.

NATIONAL DISTRIBUTION

The disease is commonest in the United States of America, where its incidence is nearly twice what it is in Great Britain. Holland and Sweden have an incidence

equal to our own, but the disease is less common in Denmark, Italy, Spain, and Greece. In the West Indies it is extremely rare among the natives but relatively common among the white population. In the villages of India and China the disease is unknown, but it is seen in the towns, both among the white population and those natives who adopt a European diet. This in fact is true all over the world. Native peoples, among whom the disease has been previously unknown, become very prone to it as soon as they live on a European diet. In seeking a cause of appendicitis the following summary of historical facts will be found helpful.

1. The disease was present, but relatively rare, in this and other countries until the end of the nineteenth century, since when it has become increasingly common in most countries. The rise in England began in 1890, and was pronounced between 1895 and 1905. From 1905 onwards it has been fairly stationary.

2. The rise was at first most marked in the towns; later the rural districts were affected, until at present the incidence is the same for town and country.

3. Inmates of institutions, living on a plain diet, are less prone to the disease than are more well-to-do people.

4. The privations of the war did not affect the frequency of the disease.

5. Appendicitis is unknown in wild animals, while it is common among animals in captivity.

THEORIES OF CAUSATION OF APPENDICITIS

As with all diseases of unknown causation, theories of the cause of appendicitis abound. One of the earliest was that it was due to the replacement, by the water-closet, of the squatting position in the act of defaecation. Another was that the fault lay with the substitution of stone flour rollers by steel ones, but no pieces of steel have ever been found in the appendix.

Of greater interest is the theory that the disease is due to an alteration in the food habits of the people, resulting in a marked reduction of the cellulose intake. During the last forty years English diet has changed very considerably, and it is of interest to examine these changes to see whether they have any bearing on the causation of appendicitis.

- (1) Since 1890 there has been a tremendous increase in the consumption of cocoa and chocolate; but these articles can be dismissed at once, since animals in captivity which develop appendicitis do not eat them.

- (2) *Bananas*.—West Indian natives eat large quantities of bananas, but they do not develop the disease.

- (3) *Butter*.—This commodity has always been plentiful.

- (4) *Meat*.—There is a very close resemblance between the increase in appendicitis and the rise in imported meat in the period 1895-1905. During these years our meat imports doubled, both beef and mutton being affected. There is no doubt but that the average consumption of meat per head of the population increased parallel to the rise in appendicitis, but if we examine the problem further we find that large sections of the community were heavy meat-eaters before 1895. In 1889, for instance, Pearce's dining-rooms in London supplied 30,000 carmen daily with a lunch containing 5 oz. of meat, and each soldier in the British Army was allowed 12 oz. of meat a day, yet the incidence of appendicitis among them was very low.

- (5) *The Reduction in Cellulose Intake*.—Between the years 1890 and 1915 the consumption of preserved meats, butter, tea, cocoa, chocolate, rice, bananas, etc., increased considerably, as has been mentioned, so that the older, coarser, cellulose-containing foods, such as swedes, turnips,

* The successful thesis entered for the Martyn Memorial Scholarship in Pathology in the University of Bristol.

concussion of the spinal cord, which produces a molecular disturbance of the grey substance, and in this way leads to progressive muscular atrophy.

Influence of Injury

The question is further discussed, with the description of another case, by Brodin, Lhermitte, and Lehmann (1931). They state that for some years they have been greatly interested in the subject of the influence of injury on the production of maladies of the central nervous system, on account of the frequency with which certain associated complications appeared which apparently resulted from a "shaking" of the spinal cord. These authors state that they were able to produce progressive muscular atrophy in dogs as a result of trauma, and that pathological examination subsequently revealed that the grey substance of the cord showed degeneration, particularly the anterior horn cells. They were greatly interested in the latent intervals which separated the date of the injury from the first manifestation of the wasting, and describe the case of a patient aged 59 whose past history was entirely uneventful.

In 1925 he was caught between a heavy plank and a ladder after having fallen down several steps, and sustained severe contusions in the region of the dorsal spine. Some months after the accident there appeared very gradually a slight weakness of the right arm. Two years later he sustained a further injury when he fell from a height on to an obstacle and was rendered unconscious.

When seen by the authors in 1931 wasting and fibrillary tremors were well marked in the arm and shoulders, particularly on the right side. There were no abnormalities of sensation, but while the cutaneous reflexes were normal the tendon reflexes were completely abolished in all four limbs. The electrical reactions were correspondingly diminished. There was no sphincter trouble, and no sensory changes were present. The vertebral column did not show any sign of injury or other abnormality.

The authors point out that the latent interval, as manifested in this case, is quite the rule and should not detract from the diagnosis of progressive muscular atrophy, for, as they have shown, it is also borne out by animal experiment.

I shall now describe the history of a patient whom I saw myself on May 22, 1936.

The patient, a man aged 62; stated that for a year and a half there had been increasing weakness in the right arm, together with occasional twitching, as well as slight numbness of the fingers. The past history revealed that forty-two years ago he had sustained a very severe depressed fracture of the skull as the result of a jack falling on his head. Some years later traumatic epilepsy ensued, and this was relieved twelve years after the injury by Sir John Lynn-Thomas, who removed a piece of bone which was pressing on the motor area. The patient stated that he had remained quite well from that time until eight years ago, when the right leg began to swell and was painful. He found, however, that he was able to compensate for this by wearing an elastic stocking.

On examination the first thing to which one's attention was drawn was a very long and deep depression involving the left parietal, temporal, and frontal regions. Then one noticed that fibrillation was very marked on both arms and on both sides of the face. Wasting of muscles was pronounced in the region of the right shoulder and the right arm. The extensor muscles of the right arm were so impaired that he was unable to dorsiflex the wrist. There was the usual wasting, resulting in a typical claw hand. The right arm was flaccid and flail-like, and all reflexes were diminished.

A thorough examination of the central nervous system failed to reveal any other abnormality. The disks were clear

and the fundus oculi was normal. The cranial nerves were normal; the pupils reacted to light and accommodation, and there was no "intention tremor" and no "Rombergism." The sense of position was not impaired, and sensation to heat, cold, pin-prick, and cotton-wool was normal. Speech was also unimpaired. The plantar reflexes were flexor, but the right knee-jerk was rather greater than the left knee-jerk. Muscular power, however, was unimpaired in the legs. The blood pressure was 130/80, and other systems of the body were quite normal.

Since I first saw the patient fibrillation of muscle has become widespread, but though wasting is more marked in the right arm it is as yet not present elsewhere.

I have quoted these cases together with the subsequent discussion at some length because, while British neurologists recognize that syphilis and acute anterior poliomyelitis are occasional aetiological factors in progressive muscular atrophy, the majority deny the association with trauma. For many years, however, eminent neurologists on the Continent have recognized that trauma is a definite causal factor in a small proportion of cases.

During the period 1925 to 1934, inclusive, thirty-one cases of progressive muscular atrophy were admitted to the Bristol Royal Infirmary, and in only three of these do the case notes include a history of injury. It is probable that this number would have been higher but for the fact that many physicians do not inquire about a previous history of injury in such cases because the importance of this is not recognized.

Commentary

There is really no evidence in favour of the idea that trauma merely "pulls the trigger" in cases where there is a congenital predisposition, nor is there any practical support for the suggestion put forward by Thiemann that an ascending neuritis occurs which ultimately involves the anterior horn cells and so produces the muscular atrophy. In the first place we do not generally find such changes with neuritis, and, secondly, symptoms of neuritis are conspicuous by their absence in the history of practically all the cases of post-traumatic progressive muscular atrophy. Localized reflex wasting after injuries of bones and joints is an entirely different condition. We are faced here with the problem of widespread progressive muscular atrophy developing in some cases years after a severe injury. It seems to me that, as some of the French authors have suggested, we are bound to assume that a molecular disturbance of brain or cord is occasioned by the injury. Is this followed by slow degeneration, or does it render the cells susceptible to the subsequent attack of an unknown virus or toxin? With regard to this it will be recalled that a most mysterious feature of the disease is the lack of correspondence between the pathological process and the symptomatology. It is possible, therefore, that degeneration of the Betz cells in the cortex and of the anterior horn cells in the cord may be occurring for some years after the injury before clinical signs become manifest.

In the present state of our knowledge, however, we can only speculate on the way in which the atrophy is brought about, and the purpose of this paper is primarily to put forward evidence that trauma is a definite aetiological factor in some cases of progressive muscular atrophy. From the medico-legal point of view alone it will be realized that this association is of very great importance.

Summary

1. Cases are described which show that trauma is a definite aetiological factor in some cases of progressive muscular atrophy.

Average Time Taken for Various Stages of Inflammation to Develop

Catarrhal inflammation	22 hours (5 cases)
Suppurative	24 " (3 ")
Gangrene	26 " (4 ")
Perforation	42 " (8 ")

Range of Temperatures found in the Series

Subnormal	2	100.1°-101°	1
Normal	1	101.1°-102°	3
98.5°-99°	5	102.1°-103°	1
99.1°-100°	7		

Range of Pulse Rates found in the Series

80-85	6	101-105	0
86-90	4	105-110	1
91-95	4	111-120	4
96-100	1		

V. Examination of the Results obtained during the Investigation**INCIDENCE OF BENT OR STRAIGHT APPENDICES**

75 per cent. of the affected appendices were markedly bent, thus confirming Aschoff's finding that bent appendices are more prone to disease than straight ones. A suggested reason for this will be given later in this paper.

INCIDENCE OF EMPTY AND FAECES-CONTAINING APPENDICES

Aschoff's opinion that diseased appendices are more often empty than full is not upheld, as 75 per cent. of the specimens contained either faecaloliths or fluid faecal matter. This finding will be referred to again in the discussion as to the causation of acute appendicitis.

PROPORTION OF CASES ASSOCIATED WITH SORE THROATS

35 per cent. of the patients complained of a sore throat. Of these, 10 per cent. suffered from chronic sore throat, and in each case the appendix was found to be chronically inflamed. In the remaining cases the patients had never had a similar abdominal pain before, and no trace of chronic inflammation could be found in 90 per cent. of the appendices. These figures are suggestive, if nothing more, and it would appear that there is an association between at least some cases of appendicitis and a slightly preceding sore throat. The series of cases examined was not, however, large enough for any definite results to be obtained.

AVERAGE TIME TAKEN FOR VARIOUS STAGES OF INFLAMMATION TO DEVELOP

Some authors are of the opinion that a definite timetable for the various stages can be made out, but this is certainly not true of the present series of cases. The average time for gangrene to develop is only four hours longer than the average for catarrhal inflammation in a total of twenty-six hours. Perforation, however, seems to be definitely later than the onset of gangrene (forty-two hours as compared with twenty-six hours). The only inference which can be drawn from this part of the investigation is that where a patient has had a characteristic pain for two days, and has a pulse and temperature of 100 or over, the appendix is probably perforated.

PROPORTION OF CASES SHOWING VARIOUS SIGNS AND SYMPTOMS

A point of interest under this heading is the low proportion—40 per cent.—of cases with constipation, which is usually regarded as being one of the most characteristic symptoms. Vomiting—90 per cent.—was a much more reliable symptom.

In 75 per cent. of the cases pain began at the umbilicus, shifting later to the right iliac fossa. This figure corresponds exactly to the incidence of faecaloliths (75 per cent.). Of the cases with faecaloliths 90 per cent. showed pain

commencing at the umbilicus, which would indicate that the initial distension of the appendix is greater in these cases than in those where only a stricture is present. The pain due to the distension is referred to the midline at the umbilicus, because the gut is developed in the midline (Arey).

Two cases showed the interesting condition of pain commencing at the right iliac fossa and later becoming localized around the umbilicus. There is no explanation of this phenomenon in the literature, but both appendices revealed the presence of chronic strictures, and it may be that the localized pain in the right iliac fossa was due to the organ being unduly near the peritoneum of the abdominal wall, so that it was infected early. Simultaneously the stricture was in effect becoming thicker from the mucosal hypertrophy which always occurs and was damming back any faeces in the distal part of the appendix. This would produce distension and consequently pain around the umbilicus.

One case showed diarrhoea instead of constipation. No aperient had been taken.

RANGE OF TEMPERATURE AND PULSE IN THE SERIES

It was confirmed that in acute appendicitis it is unusual for the temperature to rise above 100°, with a corresponding increase in the pulse rate.

INCIDENCE OF FAECALITHS AND STRICTURES

Perhaps the most important point on which the results of this investigation differ from those of Aschoff is in the incidence and importance of faecaloliths. Aschoff holds that their presence is purely fortuitous, and that the inflammation begins not around them but distal to them. In the present series faecaloliths were found in 70 per cent. of cases and strictures in 45 per cent.: only 15 per cent. were free from either. In 20 per cent. both faecaloliths and strictures were seen. Aschoff's finding that the tissue around the faecalolith was not affected was not upheld in a single case. In every instance there were inflammatory changes of various degrees in the tissue around the faecaloliths. In some cases there was chronic thickening, in others catarrhal inflammation, while two appendices were actually perforated around the faecalolith. Of their importance, then, there can be no doubt, and the suggestion is made that they play an important part in the causation of acute appendicitis, upon the following lines.

For some as yet unknown reason faecal matter in the appendix becomes inspissated to form a hard structure—the faecalolith. It is possible that its formation is linked up with the reduction in the cellulose intake, suggested by Mr. Rendle Short to be the cause of the present widespread nature of appendicitis. I would suggest: (a) That if the caecal contents are bulky from the presence of much cellulose the faeces will not enter the appendix as easily as do the very fluid faeces associated with a low cellulose diet. Hence faecaloliths would only be able to form in a smaller number of appendices, because a larger proportion would not contain any faeces for them to form from. (b) That once the faeces had entered the appendix the mucosal glands absorbed water from them. Now in the case of the faeces from a low cellulose diet the result is a hard mass which easily becomes impacted, but where the faeces contain a high proportion of cellulose the result is a softish fibrous mass which can easily be extruded and which would never evoke the inflammatory response which the hard faecalolith calls forth.

Once the faecalolith has been formed it is regarded by the appendix as a foreign body, so that an inflammatory

carrots, parsnips, leeks, and cabbages, have been crowded out, and it is suggested that this reduction in the cellulose content of the diet is at least a prominent predisposing cause of appendicitis. The following points are of importance in this connexion:

(i) The time incidence is correct. Both occurred between 1895 and 1905.

(ii) Cellulose foods were in favour longer in the country than they were in the town, whereas nowadays country and town diets are alike.

(iii) In institutions the older, cheaper cellulose foods persisted longer than among the well-to-do.

(iv) Apes in captivity do not get the coarse fibrous food they do in the natural state.

(v) Rabbits on a cellulose-free diet get appendicitis.

(vi) The disease is also very common among the inhabitants of Tristan da Cunha, who live on an exceptionally low cellulose diet owing to the impossibility of growing cereals on the island.

OTHER CAUSATIVE FACTORS

1. It has been suggested that there is a relation between appendicitis and sore throats.

2. Trauma has inevitably been suggested as a cause.

3. Foreign bodies are sometimes found in inflamed appendices and may be at fault. Especially is this so when the foreign body is one, or more, oxyuris.

4. Faecal concretions are present in 15 to 20 per cent. of cases and in 10 per cent. of apparently normal appendices. Kroghs found concretions in 35 per cent. of perforated appendices and in 27 per cent. of non-perforated appendices.

5. Kinks of all kinds have been accorded a causative function.

6. The disease has been said to follow chronic intestinal stasis.

II. The Bacteriology of Acute Appendicitis

Aschoff has done a considerable amount of work on the bacteriology of the disease, and gives his results in his monograph on appendicitis. The point he stresses is that the distal part of the appendix, where the inflammation usually starts, has a special bacterial flora of its own, different from that of the proximal part of the organ and certainly very different from the caecal flora. As examination proceeds from the proximal to the distal end of the organ there is first a reduction in the larger bacteria, especially of the spore-bearing organisms of the gas-gangrene group. There is a similar but less rapid reduction in the coliform Gram-negative organisms. The closer one gets to the apex the more Gram-positive organisms there are, but the larger cocci, streptococci, and diplococci disappear, until there only remain fine Gram-positive diplococci and rods (enterococci A and B, haemolytic streptococci). Smears from acute appendices do not usually show a pure culture; some coliform Gram-negative organisms are always present and may even be in pure culture. This bacterial flora is found equally in healthy and acutely inflamed appendices, and the important question arises as to how the fine Gram-positive organisms at the apex suddenly take on an increased virulence, sufficient to cause an acute inflammation of the organ. To this question Aschoff knows no answer. Ricker states that it is due to a circulatory disturbance of nervous origin, causing haemorrhagic infarction of the mucosa through which the organisms can enter. But appendices removed early in the course of the disease do not show this, and Aschoff maintains that no demonstrable circulatory disturbances arise.

Stagnation of Faeces.—Aschoff's experience is that acute appendicitis occurs more often in empty appendices than in those containing faecal matter, and he dismisses the presence of faecaliths as being purely fortuitous. He points out that the inflammation begins *distal* to the faecalith, not around it. (These points are discussed later.) Contrary to Rendle Short, Aschoff holds that diet is of no importance, except that perhaps the amount of food taken may be of some consequence. In his opinion figures concerning frequency of the disease among the various classes of people are useless, as they only take into account the cases which come to operation. But he is probably wrong here, for in such a disease the total incidence and the number of cases operated upon run parallel to each other. Aschoff believes that curved or bent appendices are more prone to the disease than straight ones.

Hilgermann and Pohl contend that the disease is caused by oral organisms which have reached the appendix; and while this may be true for the very few cases in which the pneumococcus has been found in pure culture, it probably does not hold generally, since one would usually expect a preceding history of rhinitis and/or pharyngitis from the virulent organisms.

III. The Purpose of the Present Investigation

This investigation was undertaken in order to elucidate, if possible, certain points about which Aschoff says more information is needed and to see whether the information gained would shed any light on the causation of acute appendicitis. In addition, a number of factors about which there is a difference of opinion and some factors of general interest were investigated. The investigation dealt with the following points:

1. The proportion, position, and importance of faecaliths and strictures.

2. The proportion of empty and full appendices affected.

3. The incidence of sore throats preceding the attack of acute appendicitis.

4. The proportion of bent and straight appendices affected.

5. The proportion of cases showing various symptoms, such as constipation, vomiting, etc.

6. The length of time taken for suppuration, gangrene, and perforation to appear in order to determine whether it is possible to construct a time-table of acute appendicitis, so that its condition may be clinically diagnosed from the time of onset of symptoms.

IV. Data obtained during Investigation

Proportion of Bent or Straight Appendices Affected

Bent appendices	15
Straight appendices	3

Incidence of Faecaliths and Strictures

Faecaliths only	14	Multiple faecaliths	..	3
Strictures	9	Neither	..	3
Faecaliths and strictures	4			

Empty or Faeces-containing Appendices Affected

Containing faecal matter	15

Incidence of Various Symptoms

Constipation	8	Pain starting in R.I.F. and		
Vomiting	18	later moving to umbilicus	..	2
Pain starting at umbilicus	15	Diarrhoea	..	1
" " in R.I.F.	3			

Incidence of Sore Throats

Acute sore throat up to 7 days before appendicitis	3
Chronic sore throat	2

It is suggested (Bruce, 1937) that the haemorrhage in the second group may be due to rupture of a miliary aneurysm or at a junctional area, and some support is given to this by the record of two patients who had a massive intraperitoneal haemorrhage from an aneurysm of a splanchnic vessel in the absence of gross arterial disease in the abdomen (Illingworth, quoted by Bruce (1937), a man of 75 with aneurysmal rupture of the middle colic artery; Budde, 1925, a man of 27 with aneurysmal rupture of the left gastro-epiploic artery).

Though from the clinical and operative findings the case described would be considered to belong to Group 1, it should, I think, be placed in the second group in the absence of any gross disease of the main abdominal blood vessels.

I am indebted to Dr. Hugh Smith for the post-mortem findings.

Clinical Memoranda

Pseudo-hypoglycaemic Attacks

In view of the anxiety and distress caused to the parents and the physician by the occurrence of hypoglycaemic attacks during the treatment of diabetes by insulin, the following case record has considerable interest and importance. In the first place, it is interesting to find a young patient—and one, be it noted, who never to our knowledge had had a genuine hypoglycaemic attack—simulate this therapeutic accident. He had, however, through association with another patient in whom hypoglycaemic attacks were the great bugbear of her parents, opportunities of learning of such catastrophes, and it is not unlikely that this was the source of his knowledge. The importance of the clinical story is that it reveals how treatment may be unwarrantably interfered with through the administration of the very article of food to which the patient is intolerant and the withholding of the very means by which this intolerance is circumvented. Indeed, in the patient above referred to as being very liable to hypoglycaemic attacks, the fear of such has led to interruption of the treatment and the rapid development of coma on more than one occasion.

CASE REPORT

The patient is a boy, aged 12 years and 9 months, who has been under observation since 1930. A sister is also a diabetic. Both children have been dieted and been given insulin, and have done fairly well. They have been in hospital on many occasions to have the diet regulated, or because of an upset of balance in consequence of a septic focus or some other intercurrent infection. The boy has been a particularly difficult patient. He resents all restrictions, and unfortunately parental discipline is very unsatisfactory.

On March 6, 1937, he was readmitted to hospital in order to start a high carbohydrate diet and for the regulation of the insulin dosage. At first an attempt was made to stabilize him

on a diet containing 66.5 grammes protein, 57.5 grammes fat, and 110 grammes carbohydrate per day. This was found very difficult: there was considerable glycosuria and slight acetonaemia. Insulin was increased from 14, 14, and 12 to 18, 18, and 16 units before breakfast, dinner, and supper respectively. The boy thought he was being kept in hospital longer than had been promised: he became more and more impatient, and was always asking when he was going home.

March 20.—At 10 p.m.—that is, four hours after his evening dose (14 units) of insulin—he was found by the nurse unconscious, cold, and clammy, with a poor pulse and unable to swallow. He was given immediately 50 c.cm. of normal saline intravenously and 15 grammes of glucose in 2 oz. of orange juice, and by 10.15 p.m. he was quite conscious and seemed better.

March 23.—The diet was changed to 70 grammes protein, 62 grammes fat, and 140 grammes carbohydrate, with 55 units of insulin daily. On this diet there was no acetonaemia, but moderate glycosuria before dinner.

March 25.—At 12.6 p.m. he received 18 units of insulin preparatory for the midday meal. Eight minutes later he became drowsy: he refused to eat his dinner. When shaken he drank some orange juice, but he kicked much, and there were peculiar jerking movements of the arms and legs, which suggested to the resident staff a convulsion. Blood was taken for sugar estimation and he was then given 20 c.cm. of a 10 per cent. solution of glucose intravenously and 30 grammes of glucose by mouth. He was quite normal at 5 p.m. The report of the blood examination revealed 0.155 grammes of glucose per c.cm., a finding which at once raised the question of the attack having been psychic in nature.

March 29.—At 12.15 p.m., about three minutes after the injection of insulin, he had another attack similar to the one described above. Blood was again taken for examination and revealed 0.148 grammes of glucose and 10.4 mg. of calcium per 100 c.cm. Nothing at all by way of treatment was given on this occasion, in view of the previous blood finding, and he came round almost at once.

April 1.—About 11 a.m. (last dose of insulin at 8 a.m.) he became drowsy and ultimately would pay no attention to anything. By 12 noon he was apparently unconscious, and neither the midday dose of insulin nor the midday meal was given. I saw him at 2.30 p.m. He was very drowsy. He refused to answer questions or do anything asked of him, but he could easily be roused by pressure behind the angle of the jaw. The pulse was of good volume and numbered 60 per minute. The opinion was expressed at the bedside that he was "putting it on" and that nothing was to be done. He was then left alone. At 3 p.m. he sat up and said that he would like to have his dinner. This was given with the usual dose of insulin. Urine passed just before the meal was yellowish-green to the Benedict test but contained no acetone. He had another attack of drowsiness at 10 p.m. which lasted for ten to fifteen minutes, but no attention was paid to him and he was soon all right.

On the following day the boy was told that he would be allowed home on a certain date and that we only wished to see how he could stand the extra sugar. From then he had no further attacks; he co-operated well and was quite contented. The diet was changed to 70 grammes protein, 35 grammes fat, and 200 grammes carbohydrate per day, with 24, 22, and 22 units of insulin before breakfast, dinner, and supper respectively. During the last week of residence there was no glycosuria and no acetonaemia, and, as promised, he was discharged on April 26, when he weighed 62½ lb.

Since dismissal in April he has been on the same diet, and since October on protamine insulin, 30 units a day. He has been well of himself, but there is still irregular glycosuria. There have been no recurrences of the above peculiar pseudo-hypoglycaemic attacks, and on December 2 he weighed 67½ lb.

response is set up around it. If the faecalith is not very big the peristalsis of the appendicular musculature may be sufficient to force it into the caecum, after which it passes along the intestine. But the inflammatory response it has evoked results in the formation of fibrous tissue—a stricture—and it is noteworthy that all the strictures in the present series were found in the same situation as the faecaliths—that is, at the proximal end of the organ. If, however, the faecalith is too large to be forced into the intestine the inflammatory response will be all the greater. The resulting oedema and compression of the surrounding tissue will compress first the lymphatics and veins, and later perhaps the arteries which drain and supply the apex of the organ. Hence it is usually at the apex that the mucosa is first seriously damaged. Once this has happened the small Gram-positive cocci and rods which Aschoff consistently found can make their way through the mucosa, become increasingly virulent, and set up an acute inflammation.

MASSIVE SPONTANEOUS INTRAPERITONEAL HAEMORRHAGE

BY

MAURICE SILVERSTONE, Ch.M., F.R.C.S.

*Honorary Assistant Surgeon, Birkenhead General Hospital
 and Birkenhead and Wirral Children's Hospital*

Massive intraperitoneal haemorrhage in the male in the absence of trauma or gross visceral disease is rare, and for that reason it was thought justifiable to put a further case on record.

Case Record

The patient, a man aged 52, was admitted to hospital with a history of a sudden onset of acute abdominal pain six hours previously. This had come on in the umbilical and hypogastric regions and doubled him up. It had since radiated to the right side of the chest and occasionally into the shoulders. On deep breathing the pain in the right hypochondrium was worse. He had had a similar attack of pain a week before. This was confined to the umbilical region and had not radiated. It had lasted three days. During the whole of the week he had had two or three attacks almost daily, the pain lasting a few seconds. There was no history of indigestion and none of trauma, but some frequency and scalding of micturition was experienced. He had been on a diet for high blood pressure and had lost 2 stone.

The previous medical history—for which I am indebted to Dr. R. O. Knowles of Birkenhead, who sent the patient into hospital—showed him to have suffered from bronchitis for some time. He had had two attacks of pulmonary oedema, as well as anginal attacks, and his systolic blood pressure was 200 mm. Hg. For this he had been dieted. He was a fairly well built man, with an emphysematous chest. On admission he was pale and somewhat cyanosed, cold, and clammy. His pulse was 96 and temperature 96.8°. The whole of the abdomen was very tender, this being especially marked in the upper abdomen and right subcostal regions. There was no real rigidity and no loss of liver dullness. In view of the shocked condition of the patient, his history and build, it was thought that he might have an acute pancreatitis. However, though there was doubt as to the actual causative lesion, there was no doubt that the case was one of acute abdominal emergency and should be explored. The pulse had remained stationary during the period before operation, being 98, and his temperature had risen to 98°.

Under spinal anaesthesia the abdomen was opened through a mid-line supra-umbilical incision and was found to be full of blood. A considerable amount was evacuated, and the hand was passed to the splenic region as it was thought that there might have been a spontaneous rupture of the spleen. Unfortunately, the spleen could not be brought into the wound, but nothing abnormal was felt on palpation. The liver, gall-bladder, pancreas, stomach, and intestines were normal; there was no retroperitoneal mass of clot, which was looked for as it was thought that the bleeding might have come from an aortic abdominal aneurysm. The kidneys felt normal, and there was no retroperitoneal collection of blood in the vicinity. The pelvis was also normal. There was staining of the mesentery and omentum, but no intramesenteric clots were present. As gross aneurysm appeared to have been excluded attention was again given to the spleen, as the quantity of blood there seemed to be greater than elsewhere. An attempt was made to bring it into the wound for inspection; this was successful, but in doing so an adhesion was torn. The spleen appeared to be normal; there was a tear in the capsule about one inch by one-quarter inch, certainly due to operative trauma. There was no pulping of the spleen or any subcapsular haematoma. As the patient's pulse was becoming very weak the abdomen was closed, a drain being left in. His pulse improved in volume once the abdomen was closed. A transfusion of one pint of citrated blood was given an hour later. After the operation his pulse rose to 150 and his temperature to 102°, and in the first twenty-four hours the pulse dropped to between 120 and 136, the temperature at the same time varying between 99.4° and 101.6°. However, thirty-six hours after the operation his pulse became weaker; he became much more dyspnoeic; and he started vomiting, dying soon after.

PATHOLOGICAL REPORT

At the necropsy the abdomen still contained a considerable amount of blood, with what appeared to be a greater proportion in the splenic region and an accumulation in an inguinal hernia sac. The stomach was dilated, and the small intestine also slightly distended but otherwise normal, as also were the liver, pancreas, kidneys, suprarenals, and bladder. The spleen was normal in size and texture. There were two tears in the capsule, each about one inch by one-quarter inch, which were considered by me to have been secondary to the operative trauma. The abdominal aorta showed only very slight evidence of atheroma. The heart was enlarged. The orifices of the coronary arteries were normal. There was slight blood-staining on the upper surface of the diaphragm. Though the individual splanchnic vessels were not carefully dissected the absence of any retroperitoneal clot was thought to exclude any aneurysmal rupture.

Comments

Cases of massive intraperitoneal haemorrhage in the male in the absence of trauma or gross visceral disease appear to fall into two main groups:

1. An older group of patients, aged 44 to 60, with marked arteriosclerosis and high blood pressure, the haemorrhage coming from a ruptured splanchnic vessel. Six cases have been described which can be included in this category; of these, two were not operated on, being discovered post mortem (Moorehead and McLester, 1936), and four were operated on. In three of the latter (Starcke, 1923; Green and Powers, 1931; Buchbinder and Greene, 1935) the bleeding point was found, the vessel was ligatured, and the patients recovered. In the fourth case (Hilliard, 1918), where no bleeding point was discovered, the patient died.

2. A younger group, in which the vascular system is healthy and no bleeding point is found. Three cases come under this heading: Churchman, 1911—a man aged 48; Hartley and McKechnie, 1934—a man aged 31; and Bruce, 1937—a man aged 34. Of these only the last-named survived laparotomy.

conventional headings of neurasthenia, hysteria, anxiety, compulsions, etc. But when we turn to such a common perplexity to the general practitioner as stammering, what do we find? "In the unconscious of many stammerers the whole body represented a penis and the mouth represented the opening of the urethra and anus. Consequently, as Fenichel says, 'The fundamental pleasure in stuttering is that of playing with words which analysis has found repeatedly to be a continuation of infantile playing with faeces, displaced from below upwards—the words being held back as faeces were held back in infancy to produce an auto-erotic pleasure.'" Again, "speech is closely related to the anal-sadistic stage of development. It is found that stutterers have been children who were very difficult to train in toilet habits or whose training itself was over-severe." Or again, in relation to the other bugbear of practice, enuresis, the enuresis of the small girl is attributed to the thwarted desire to be impregnated by the father, and the revenge is taken by the production of "a urinary baby." In both these conditions the authors admit the value of retraining, but hold that the disclosure of the hidden motives such as the above by psycho-analysis is by far the most valuable and useful line of treatment.

It is possible that these conceptions of infantile sexuality may be useful to those who, having made a life-study of the subject, thoroughly understand the genesis, development, and application of the concepts, but we cannot imagine that the general practitioner or the medical student is going to get much help or advantage from a short and rather superficial exposition of them. We would advise those who are interested in "Freudian psychology" to submit themselves to the discipline of a complete study of the subject, and unless they are prepared to undertake that task it is unlikely that this or other similar books will do anything but mystify and mislead them.

THE UROLOGY OF CHILDHOOD

Pediatric Urology. By Meredith F. Campbell, M.S., M.D., F.A.C.S. With a Section on *Bright's Disease in Infancy and Childhood* by John D. Lytle, A.B., M.D. (Vol. i, pp. 570; Vol. ii, pp. 540; 610 figures, 2 coloured plates. £3 3s.) New York: The Macmillan Company. 1937.

Recent years have seen a greatly increased interest in the genito-urinary tract of children and its disorders, partly due to the ingenuity of the surgical instrument manufacturers, and the time is ripe for a comprehensive textbook on the subject. Few if any specialists in this branch of surgery are better qualified than Professor Meredith F. Campbell to write such a book, and his *Pediatric Urology* will be welcomed by all those, physicians and surgeons alike, who deal with sick children. The work is divided into two volumes (each with an index covering both), and there are over 1,350 illustrations, including two coloured plates. In the first volume Professor Campbell discusses methods of examination and diagnosis, and there is also a long chapter on the anatomy, physiology, embryology, and anomalies of the urogenital tract. The other two chapters in this part are concerned with obstructions of the urinary tract and with urinary infections. The second volume contains chapters on diseases of the genital organs, injuries, calculus, tumours, enuresis, and the special surgery of the genito-urinary tract in childhood. Dr. John D. Lytle contributes a valuable account of Bright's disease in infancy and childhood—for Professor Campbell holds that the urologist should be as conversant with medical as with surgical diseases of the kidney. There is also an

interesting chapter on disorders of the neuro-muscular mechanisms of the urinary tract.

The first impression of these two beautifully produced volumes is that the author has performed his task in a thorough manner. He explains in a preface that it has taken ten years to do this, and the extensive bibliographies given at the end of each chapter indicate that he has drawn not only on his own extensive experience but also upon the experiences of others in a vast and increasing volume of literature. Random sampling of sections likely to contain controversial matter provides evidence of a balanced judgment, and opposing views are fairly quoted and criticized. Professor Campbell is perhaps pessimistic when he states that "about half of all children suffer from a form of urologic disturbance before they reach puberty." Even, however, if such a statement is somewhat exaggerated, paediatricians are likely to encounter in their daily practice many of the disorders described in this monograph, and it is probable that these volumes will afford great help to them in arriving at a full understanding of this branch of their work.

LOCAL IMMUNITY

Les Immunités Locales. By A. Besredka. (Pp. 224; 35 fr.) Paris: Masson et Cie. 1937.

Professor Besredka's original book on local immunity is out of print. He has now written a new book on the subject, including much recent material. A large part of this is made up of records of successful applications of local immunization, with vaccines or antiviral, both among animals and man. Among the most striking examples are those of oral immunization against typhoid fever. There is little reference to adverse criticism or unsuccessful experiences. In places Professor Besredka wanders away from local immunization and discusses the superiority of intradermal inoculation as a method of producing general immunity. He also discusses the advantages of injecting antisera near the site of invasion, when passive immunization is employed.

It seems that local immunity can appear in the absence of circulating antibodies. The whole question is therefore wrapped up with that of cellular immunity. Professor Besredka gives a short account of experiments showing the development of immunity in plants, in which the action of circulating antibodies can hardly be invoked.

A GUIDE TO GYNAECOLOGICAL AND OBSTETRIC NURSING

Obstetric and Gynecologic Nursing. By Frederick H. Falls, M.S., M.D., F.A.C.S., and Jane R. McLaughlin, B.A., R.N. (Pp. 492; 83 figures. 12s. 6d. net.) London: Henry Kimpton. 1937.

One of the great faults inherent in the modern method of nursing instruction is that so much attention is directed to purely theoretical subjects that actual nursing technique is reduced to a minimum. It is no doubt essential that the pupil should have a knowledge of the fundamentals of anatomy and physiology, but the tendency to treat her as a kind of second-rate medical student must inevitably detract from her efficiency. This tendency is well shown in the contents of many textbooks and examination papers, some of which imply a standard of medical knowledge at once unnecessary and unattainable. It is for this reason that the latest addition to the literature on the subject is particularly welcome, for while much information of a purely medical character is included, it is given simply and succinctly, and is used mainly as

Reviews

CONGENITAL DEFORMITIES OF THE EYE

Developmental Abnormalities of the Eye. By Ida Mann, D.Sc., M.B., F.R.C.S. With a foreword by Sir John Herbert Parsons, C.B.E., D.Sc., LL.D., F.R.C.S., F.R.S. (Pp. 444; 284 figures. 50s. net.) Cambridge: The University Press. Published for the *British Journal of Ophthalmology*. 1937.

Not so many years ago every congenital deformity of the eye was regarded as the result of a hypothetical intra-uterine inflammation. This conception was itself a reflex of the dominant place that inflammation occupied in general pathology. With fuller appreciation of late years as to the aetiology of disease the multiplicity of factors that may lead to disturbances has come to be recognized, and it is clear that no monistic conception of disease is likely to be valid. Endocrinology, the study of vitamin deficiencies, allergy, and immunity have all affected ophthalmology, but none so markedly as the study of inheritance of disease. Indeed ophthalmology, largely through the pioneer work of Nettleship, was instrumental in guiding other disciplines in this direction.

The modern outlook as applied to maldevelopments of the eye is ably brought out by Miss Ida Mann in her monograph. This is a subject that bristles with difficulties: even the descriptive terms used are exasperating monuments of our ignorance on fundamentals. Such a seemingly innocuous term as "congenital" hides endless difficulties. Chronologically, any injury or disease present in a newborn baby would be regarded as congenital, yet an apparently perfect infant may be the subject of an affection that will make itself manifest later on in life, and which none the less is something that it carried from the days before its birth—retinitis pigmentosa being a case in point. Indeed, birth is itself but a point in a continuous biological development. It is conceivable that a maldevelopment might be due to mechanical interference during foetal and embryonic development, and this has in fact been proved to be the case by experimental embryologists. Yet clinical experience has emphasized the great significance of heredity in many maldevelopments. As it is known that the placenta is not an absolute barrier for the protection of an embryo against noxious substances in the mother's circulation, and that considerable disturbances do occur in the medium in which the embryo grows to natal maturity, the question arises as to how to assess the relative value of these factors on the one hand and of predetermined genetic influences on the other. To that problem no final answer is as yet possible. No balance between genetics and embryology has yet been achieved, and Miss Mann has put ophthalmology under an obligation by her skilful compilation of the clinical data available and her critical review of the likely mechanism in the different groups of maldevelopment.

So much has been achieved by embryologists in the recognition of dissimilar disturbances produced by similar influences at different times in embryonic development that the temptation is strong to see in maldevelopments permanent witnesses of such disturbances at particular times, and to rest on the safe ground of experimental observation.

Miss Mann has written a book with a strong bias in the direction of embryology: the emphasis is not always that which would have been given by other writers, especially geneticists, but the facts are there from which

the reader may draw his own conclusions. Those to whom the minutiae of embryology are deep waters will find simple and clear accounts of the clinical aspects of an important branch of ophthalmology. The references, while not exhaustive, are ample and exceedingly helpful. On the scientific side the book is a contribution that is bound to influence the development of British ophthalmology.

DISEASES OF THE EAR, THROAT, AND NOSE

Diseases of the Ear, Throat, and Nose. By J. Douglas McLaggan, M.A., M.B., F.R.C.S. Eng. & Ed. (Pp. 338; 9 plates, 135 illustrations. 15s. net.) London: H. K. Lewis and Co. Ltd. 1937.
Quelques Vérités Premières (Ou Soi-Disant Telles) en Oto-Rhino-Laryngologie. By M. Ombrédanne. (Pp. 86. 24 fr.) Paris: Masson et Cie. 1937.

Under the first title Mr. J. D. McLaggan has contributed a volume to Messrs. Lewis's General Practice Series. The author has chosen his material so as to offer a full account of those simpler methods of examination and treatment of common diseases that may be required daily in general practice. Endoscopic examination and the more elaborate operations are not included, though a few which the general practitioner is not likely to perform are described in some detail. The book may thus be said to achieve the aim of providing an account of everything which the practitioner is likely to undertake, and even a little more; but it fails to give even an outline of all that can be done by the specialist for these patients. The book, as intended, should be helpful in general practice, but is not suitable for house-surgeons or clinical assistants.

Dr. M. Ombrédanne presents in the form of a series of aphorisms a complete exposition of the principles upon which the practice of otology and laryngology is based. In a book of fewer than ninety pages he tells in laconic sentences all that a beginner needs to know in order to obtain a comprehensive grasp of the subject. There are neither illustrations nor superfluous words, and we are shown how much information can be packed into a little space without making it unreadable. Nor are a few flashes of worldly wisdom lacking. This is written of the removal of wax from the ear: "Si c'est une femme coquette à qui vous avez rendu ce service, laissez-la réjouir du résultat obtenu. Mais ne lui montrez pas le corps du délit; elle vous en voudrait mortellement de vous être permis de supposer qu'elle avait les oreilles sales!" This book is warmly recommended.

COMMON NEUROSES

Common Neuroses of Children and Adults. By O. Spurgeon English, M.D., and Gerald H. J. Pearson, B.A., M.D. (Pp. 320. 12s. 6d. net.) London: George Allen and Unwin Ltd. 1937.

The very multiplicity of books which seek to expound Freudian doctrines to the general practitioner and the medical student shows how difficult is this task. Each author is dissatisfied with the attempts of his predecessors, and full of enthusiasm embarks on the hopeless task himself. In such books the table of contents is always promising, and the one under notice is no exception. Part I covers the structure of the personality, normal development, and the factors which interfere with this and the method of symptom formation. Part II is devoted to the common neuroses of childhood, comprising vegetative and motor and sensory disturbances, social maladjustments, delinquencies, etc. In Part III the common neuroses of adults are discussed under the

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 29 1938

OXYGEN WANT AND OXYGEN THERAPY

During the past fifteen years our knowledge of anoxia (oxygen want) and oxygen therapy has been extended and clarified in many directions. Two concise reviews in book form have been published within the past few years. The first of these was written by two researchers in this country.¹ The second review, which is French, appeared quite recently, the author being Dr. L. Dautrebande, professor in the faculty of medicine, Liège.² Very fittingly he has dedicated his volume to the late J. S. Haldane, the leading authority of modern times in the study of respiration. A third volume³ which touches on parts of these subjects has been reviewed in this *Journal* (October 30, 1937, p. 854).

Although a great deal of information was to hand, from the Haldane and Barcroft schools of research, regarding the effects of oxygen want on respiration and blood gases respectively, what was actually happening in the cells and tissues was not so clear. This required more direct study of gas pressures in the tissues themselves.⁴ Normally in the resting subject the oxygen pressure in the extracellular fluids—for example, serous fluid, lymph, urine—and probably in the cells themselves, is certainly not zero, but varies for different regions between 20 and 40 mm. Hg, or 3 to 6 per cent. atmosphere, while the carbon dioxide pressures are about 40 to 60 mm. Hg, or 6 to 8 per cent. As might be expected, these figures, which apply to man and all laboratory mammals tested, resemble the pressures usually given for gases in venous blood. Effects of oxygen want and oxygen therapy upon tissue gas pressures may be easily tested with experimental animals. Thus acute oxygen want, apart from the histotoxic variety—for example, poisoning with cyanide, which affects the ferment system—always lowers the oxygen pressures in the tissues considerably, and if the fall is much below 40 per cent. of the normal death results. Life is not possible with a tissue oxygen pressure in general anywhere near zero. Locally a zero oxygen pressure is approached only where there is pus, necrosis, and

stasis of circulation—for example, in pyopneumothorax or in the large intestine with food present and fermentation proceeding.

As regards acclimatization to the more severe degrees of oxygen want, the oxygen pressure in the tissues is not raised to normal again even when there is increase both in volume breathed and in red cell count. Such increases seem to be used not to raise the tissue oxygen pressure to normal again but to relieve the work of the heart that is to limit the minute output. Acclimatization is due to the vital organs becoming accustomed to function under the lowered tissue oxygen pressure. Possibly there are changes in the cells concerning such substances as the glutathione of Sir Frederick Gowland Hopkins and the reactions described by Professors Warburg and Keilin. Oxygen secretion, if it does occur in the lungs, is—like any other factor in the body—not capable of keeping the oxygen pressure in the tissues at a normal level during severe degrees of oxygen want. Another important result is that administration of oxygen—even in only double the normal (21) percentage—definitely raises the oxygen pressure in the tissues in a normal animal. This affords the scientific basis for oxygen therapy.

Concerning the powers of endurance, it is found⁵ that mammals cannot live continuously in regions where there is only 10 per cent. or less of oxygen in the atmosphere; this is equivalent to an altitude of about 20,000 feet. Such degrees of oxygen want cause atrophy, degeneration, and even necrosis in the liver, heart, brain, and other organs.^{1, 2, 6} This limit of 10 per cent. was first established with laboratory mammals, and has recently been confirmed for a highly selected community in the South American Andes, as recorded by Dr. Ross McFarland.⁷ Some sulphur miners there work at a slow pace at 19,000 feet, but find that they cannot continue in health if they sleep and live continuously above 17,500 feet. Their camp at 17,500 feet is claimed to be the highest permanent village in existence. The miners descend to 12,000 feet for a proper game of football and also send their wives to this level for confinement, though fertility appears to be maintained at 17,500 feet, where the arterial blood saturation with oxygen is about three-quarters of normal. It is obvious that the Everest climbers should not spend too long camping above 18,000 feet. Some of these climbers, like the experimental animals, have exhibited some temporary resistance, but, since at 27,000 to 28,000 feet the climbers are reported to have suffered from delusions and to require ten breaths for each step forward, oxygen should be at

a necessary basis for the more practical description of the various treatments involved.

Written jointly by the medical and nursing directors of a large obstetric and gynaecological department, the book is devised more particularly for qualified nurses practising in these subjects, and is meant to supplement rather than to replace the more standard works. Most of the methods described are those employed in English hospitals, though exception might be taken to the routine use of lysol, the administration of pituitrin for retained placenta, and the somewhat violent technique for the resuscitation of babies. The purely medical opinions expressed are also mainly orthodox, though there are some notable omissions—for example, the mandelic acid treatment of pyelitis, the importance of insomnia in pregnancy toxæmia, and the prevention of spread of puerperal sepsis. It is also stated that one-child sterility is due to gonorrhoea, that amenorrhoea is rare in ectopic gestation, and that syphilis is a common complication of pregnancy. But apart from these points, and inevitable Americanisms like "hypodermoclysis," "eclamptogenic," "gavage," etc., the book is a valuable contribution to specialized nursing, and should be studied by all those engaged in its practice.

Notes on Books

It is thirteen years since Dr. LOGAN CLENDENING, clinical professor of medicine in the University of Kansas, brought out *Methods of Treatment*, which contains chapters on special subjects by ten collaborators; and that the book is now in its sixth edition (Kimpton, 42s.) is eloquent evidence that it meets a definite demand. The revision has brought the text into conformity with the eleventh edition of the *United States Pharmacopoeia*; the author has departed from his conservative view about the use of artificial pneumothorax, and in the rewritten chapter expresses agreement with the general opinion. Other changes and additions have been duly made.

In his *Short Dictionary of the History of Medicine* (Jena: Gustav Fischer, 1937, RM. 9, paper; bound, 10.50) Professor B. MAYRHOFFER, head of the Museum of the History of Medicine and formerly rector of the University of Innsbruck, has compiled an excellent work of reference which will be of value not only to the medical historian but also to the practitioner who can read German and takes an intelligent interest in the history of his profession. Within the short space of 224 pages Professor Mayrhofer has accumulated an immense amount of interesting information, including short biographies of eminent doctors and men of science, and a brief description of the most important diseases, drugs, operations, and schools of medicine in all ages. Errors are few and comparatively trivial, such as the omission of Klebs in the mention of the diphtheria bacillus, the attribution of the death of John Howard, the prison reformer, to plague instead of to "camp fever," as typhus was then called, the addition of a superfluous terminal "n" to the name of Sir William Bowman, the substitution of "Paul" for Pierre as the Christian name of Bretonneau, and the date of birth of Sir Frederick Banting as 1991.

In a pamphlet entitled *Prejudicial Assumptions in Poison Cases* (Westhope and Co., 6d.) Miss ALICE RAVEN, barrister-at-law, declares that juries in our criminal courts of assize habitually adopt a prejudiced attitude towards accusations of murder by arsenic. They assume without sufficient evidence, she says, that a lethal dose of arsenic is the cause of death; that previous gastro-intestinal trouble is due to arsenic; that arsenic found in the body was criminally administered; that it was given by the person with the best opportunity; and that to such a

person any benefit accruing from the death is a sufficient motive. She supports these criticisms with an analysis of the Maybrick and the Bryant cases. It is a little surprising to learn that the judges of the King's Bench, whose duty it is to direct juries and later to correct their mistakes on appeal, have these serious blind spots in their otherwise admittedly keen and well-trained eyes. No doubt they will be grateful to Miss Raven for pointing out their shortcomings, and think themselves fortunate in having a critic so free from their disadvantages of training and experience.

The Rickman Godlee Lecture, *The Price of Progress*, delivered by the Very Rev. W. R. INGE at University College, London, on November 22, 1937, is now published, and may be obtained on application, enclosing postal order, to the secretary, University College, Gower Street, W.C.1. (Price 1s.; post free 1s. 2d.)

H.M. Stationery Office has issued in pamphlet form abstracts of the official papers, numbering 140, published from the National Physical Laboratory in the scientific and technical press during the year 1936. It is the first of a series which will be continued annually. The purpose of the abstracts is to provide a concise summary of the completed work of the laboratory, supplementing the information given in the annual reports. An author index and a subject index are included. The price is 1s.

Preparations and Appliances

VITAMIN PREPARATIONS

"Nestrovite" (Roche Products Ltd.) is a preparation of vitamins issued as emulsion and as tablets. It is the result of prolonged researches undertaken with the aim of providing the four indispensable vitamins (A, B₁, C, and D) in a form both pleasant to take and medicinally reliable. One teaspoonful of "nestrovite" emulsion contains the following vitamin content as measured in international units: vitamin A, 5,000; vitamin B₁, 42; vitamin C, 135; and vitamin D, 500. A single tablet contains about one and a half times each of these amounts. These quantities are approximately equivalent to one teaspoonful of cod-liver oil, two teaspoonfuls of orange juice, plus an adequate daily dosage of vitamin B₁.

Both preparations are very palatable and provide a simple method of ensuring an adequate supply of all the essential vitamins. The prices are: 3s. 3d. for a 4½-oz. bottle of emulsion and 14s. for 100 tablets. The marketing of this price of a preparation containing four vitamins in a purified form is striking evidence of the rate at which vitamin chemistry has advanced in recent years.

CALCIUM MANDELATE

Calcium mandelate (Burroughs Wellcome and Co.) is stated to be entirely free from the unpleasant taste which characterizes the soluble salts of mandelic acid (that is, sodium or ammonium mandelate). The mandelic acid is absorbed but not the calcium, and hence the degree of urinary acidity produced is equal to that produced by ammonium mandelate and superior to that produced by sodium mandelate. The manufacturers claim that the compound makes effective mandelic acid treatment possible without the setting up of digestive disturbances. The normal adult dose recommended is 4.4 grammes of the powder, which is equivalent to 3 grammes of mandelic acid.

CAPSULES FOR FURUNCULOSIS

"Glesol" capsules (prepared by the French house of Couturier, Paris, and marketed in this country by Savory and Moore Ltd.) are stated to contain a yeast extract, colloidal tin, colloidal sulphur, lactic ferments, and a gluten coating. They are recommended for furunculosis and other staphylococcal infections.

the treatment is unsatisfactory, or at best uncertain. There are a few obvious causes, such as congenital maldevelopment of the vertebrae, nervous diseases—of which poliomyelitis is the most important—intrathoracic disease—generally empyema—and rarities such as von Recklinghausen's disease. But when all these have been eliminated we are left with a substantial majority in which no obvious cause is present. An immense amount of energy has been expended in trying to explain these "idiopathic" cases. Yet so far no theory, let alone scientific proof, of the causation of lateral curvature has managed to command wide acceptance. It is best to be honest and admit that we do not know. The circumstances attending the appearance of this sinister curvature, which may progress until the patient is hideously deformed, are well known. Girls are affected more often than boys, and the trouble generally begins during the years of puberty—though it may appear any time during childhood. Postural curves, antero-posterior and lateral, develop during the same period, but they are unaccompanied by the structural changes, of which wedging of the vertebral bodies is the most obvious, so characteristic of scoliosis.

Two obvious lines of investigation suggest themselves. Can we find evidence of some obscure bone malacia which causes the spine to buckle under the severe and constantly changing stresses of the growth period? The answer so far has been in the negative, and it is significant that rickets, about which we know a great deal, does not cause scoliosis, unless the disease is of unusual severity. Can we, on the other hand, find a neurological condition which will upset the delicate balance of the muscles controlling the spine? Poliomyelitis comes to mind immediately, and must not be lightly dismissed. We are all familiar with the case of unilateral pes cavus, sometimes accompanied by a little shortening of the affected limb, insidious in onset, and dating from nothing in particular. It is reasonable to suppose that this deformity is the result of poliomyelitis, which was so mild in its acute phase as to escape attention. There are cases in which the abdominal muscles, and apparently no others, have been similarly affected, and a scoliosis has resulted. It is just possible that many "idiopathic" curves are due to the same condition in more deeply situated muscles for which at present there are no satisfactory methods of examination. During the past summer we have been reminded of the ubiquity of the poliomyelitis virus in this country, and it is possible that one of its more remote crimes is the production of lateral curvature of the spine; this line may be worth following.

But why girls rather than boys? On another page Dr. R. G. Abercrombie has advanced a hypothesis which postulates abnormality in an entirely different sphere. He suggests that the trouble is psychological—due to what he calls "bashfulness." There is no doubt that girls at puberty often become "all girlish" and that they are acutely conscious of changes in their physical condition. It has often been noticed that they try to hide the most obvious change by assuming a hunched-up (kyphotic) attitude, and that explanation and reassurance rather than exercises will generally cure the condition. Yet it is hard to believe that faulty posture due to excessive bashfulness can lead to the development of serious structural changes, often the beginning of a lifetime of trouble. This new approach is interesting, perhaps valuable: but we would like to see more evidence, properly documented. Has Dr. Abercrombie got a definition and standard of bashfulness? Is there any hope of independent observers agreeing on their findings after examination of the same series of children? How many bashful children fail to develop scoliosis, and what about bashfulness in boys? Mr. Philip Wiles¹ has recently investigated postural antero-posterior curvatures in adolescents. He found a psychological element among the responsible factors, but he also found an organic abnormality (pelvic inclination) of even greater importance. How much more, then, are we likely to find an organic cause for the serious organic derangement so typical of scoliosis, but perhaps with psychological disturbances as a contributory factor!

ANTI-SCARLATINAL SERUM IN ACUTE RHEUMATISM

The relation of haemolytic streptococcal infections of the throat to acute rheumatic fever has been demonstrated in a convincing manner during the past few years, and this, coupled with a growing dissatisfaction with the immediate and remote results of the use of salicylates, has led J. Eason and G. Carpenter² to study the action of anti-scarlatinal serum in rheumatic polyarthritis and chorea. Their communication deals in detail with just under fifty cases, and the results may be fairly described as encouraging. A stock concentrated anti-scarlatinal serum supplied by Parke, Davis and Co. has been used throughout, all patients being tested first for serum sensitivity. Non-sensitive patients received 30 c.cm. of serum intramuscularly, and this was repeated in thirty-six hours. Sensitive patients were desensitized and the full dose given gradually. There were some departures from this programme—for example, in the case of patients too ill with carditis to receive the full 20 c.cm. at once. Thirteen cases of

² *Quart. J. Med.*, 1937, 6, 93.

hand to prevent further calamity in these very high regions.

That mammals cannot live continuously in an atmosphere containing only 10 per cent. of oxygen leads to interesting conjectures. Some authorities hold that at one early period of the earth's existence there was no free oxygen in its atmosphere and life was anaerobic; the oxygen now present was freed, under the influence of the sun, by that green plant life which laid down enormous deposits of coal. Dr. W. M. Clark, who has carried out important researches on oxidation-reduction potential, considers that oxygen is a scavenger clearing up the waste products of cell metabolism by combustion. From the above it might be tentatively suggested that when mammals were first sprouting from the tree of life the oxygen present in the surrounding atmosphere had risen above 10 per cent., and that is why mammals cannot now become acclimatized to lower oxygen pressures. When the condition of a patient with oxygen want resembles that of an individual forced to breathe less than 10 per cent. of oxygen continuously recovery is impossible.

Turning to modern oxygen therapy, the late J. S. Haldane and others—including Professor Dautrebande²—have much improved the mask method employed by Beddoes (1760–1808) at Bristol; he and Chaussier (1780) appear to be among the first to administer oxygen to patients.¹ Some of the present forms of mask apparatus are too heavy for weak patients but are inexpensive to run and of service for the stronger patients. Sir Leonard Hill introduced the recent chamber and tent methods, but the first comfortable chamber was that of Sir Joseph Barcroft at Cambridge, while tents have been much improved by Dr. A. L. Barach and others. The chamber, or room, methods are the most comfortable, but running expenses are high. Even the simplest tents—for example, the Guy's Hospital tent and the open-top tent of St. George's Hospital in this country—though cheaper than oxygen chambers, cost up to about thirty to forty shillings a day to run, and often demand constant skilled attention. Still cheaper and simpler methods for nurses are the twin catheter method, the forked nasal tube, and the box mask or face tent; the nasal methods cannot be used with blocked nasal passages. Sir Arthur MacNalty includes the references and gives the most recent comparison of all these methods in his annual report (1936) to the Minister of Health. Tents seem valuable for children and for the more restless patients.

Oxygen therapy should of course be used in all cases of excessive dyspnoea and asphyxia as emergency treatment. Also in diseases with cardio-respiratory embarrassment it may certainly keep

a patient alive and enable other therapy—for example, serum in pneumonia—and natural processes to produce a favourable result. Pneumonia, the disease most frequently treated with the aid of oxygen, is responsible for about 500,000 patients, with 100,000 deaths, a year in the United States, where much research is being directed towards reducing this incidence and mortality. With less than half the population of the United States, England and Wales (1936) had 46,000 cases, with over 30,000 deaths. The value of early treatment with oxygen—within the first six hours of onset—in lessening serious complications seems to have been proved in America. Pure oxygen should be used for short periods only—a few hours—the limit recommended for prolonged treatment being 60 per cent., since with higher percentages the late Lorrain Smith found evidence of damage to lung tissue.

Professor Yandell Henderson's advocacy of carbon dioxide as a respiratory stimulant is justified; for carbon monoxide poisoning 7 per cent. carbon dioxide with 93 per cent. oxygen gives the best results, according to a prolonged test in the New York emergency service. In anaesthesia and asphyxia neonatorum 5 per cent. carbon dioxide with 95 per cent. oxygen is useful. Dame Louise McIlroy's apparatus is simple and efficient with the newborn. Artificial respiration is often used in conjunction with oxygen therapy; the Sharpey-Schafer method is still the simplest and most efficient for general purposes, and there is also the recent rocking method of Dr. Eve. The Bragg-Paul pulsator for rhythmical compression of the chest is simple and useful for prolonged periods: it kept a patient with progressive muscular atrophy alive for some years. The Drinker apparatus, although complicated, is perhaps the most physiological, and has been much used in respiratory paralysis. Some recent and fairly full data³ seem to show that with this Drinker treatment only about 10 per cent. of the cases with bulbar respiratory paralysis eventually recovered, as did about 30 per cent. of the cases with spinal respiratory paralysis; nevertheless the immediate and dramatic value of the apparatus is obvious.

LATERAL CURVATURE

If some inquisitive wag circularized the orthopaedic surgeons of this country and asked them—confidentially—what condition baffled, bored, and irritated them more than any other it is probable that most of them would unhesitatingly answer scoliosis. The causes of structural lateral curvature of the spine are for the most part unknown, and

³ Current comment (1937). *J. Amer. med. Ass.*, 109, 1130.

mitted to a rigorous inspection, and a long questionnaire, dealing with the structure of the vessel, accommodation, food, water supply, sanitation, and deratization, has to be answered. Pilgrims are not allowed, as formerly, to bring their own food and individually prepare it: loud speakers inform them when meals are ready for being eaten under sanitary conditions. Medical surveillance is maintained throughout the voyage. Ample arrangements for camp hygiene are made. Improved water supply and drainage, installation of electric lighting, refuse destructors, disinfectors, clean kitchens and bedding all have the effect of keeping the general health good. Some 16,700 pilgrims passed through the quarantine camp at Tor, where examinations of stools, blood, and sputum of any suspected cases were undertaken. These measures found the pilgrims appreciative of all the efforts made for them. A programme of steady improvement in the encampments during the past ten years has thus been rewarded by excellent health conditions among these thousands of more or less irresponsible devotees who congregate at the two holy cities. These annual printed reports form a useful record for reference in the management of mass movements of people under tropical hygienic superintendence.

EMANUEL SWEDENBORG

On January 29 the 250th anniversary of Emanuel Swedenborg's birth will be commemorated by a meeting to be held in the Queen's Hall, London, under the chairmanship of the Swedish Minister, Baron Palmstierna. A many-sided genius who, like Aristotle, Leonardo da Vinci, Goethe, and Thomas Young, took all knowledge for his province, Swedenborg was a physicist, mathematician, chemist, physiologist, astronomer, geologist, philosopher, poet, and theologian. He designed a submarine to attack ships under water, sketched a flying machine, manufactured lenses, designed an ear-trumpet, invented a new stove, was a skilful engraver and book-binder, and an active reformer in the House of Nobles. Though he understood the anatomy and physiology of the spinal cord better than his contemporaries, it was the physiology of the brain which particularly fascinated him because he was searching for the seat of the soul. Psychological activity he believed to reside in the smallest cortical elements hanging at the ends of nerves (nerve cells), different departments of activity being localized in different parts of the cerebral cortex. He further localized the motor centres in the cortex and knew of the relation between the corpora quadrigemina and the movements of the eyes. At a time when methods of investigation were few and imperfect he was interested in the ductless glands, and his constructive imagination anticipated many later discoveries. Appointed assessor of the Royal College of Mines in 1716, Swedenborg held this post until 1747, when he decided to devote his life to the contemplation of spiritual matters. He died in 1772. The first of the English Swedenborg Societies was founded in London four years after his death and became afterwards known as the "London Universal Society for the Promotion of the New Jerusalem

Church." The present Swedenborg Society was established in 1810. First and rare editions of his works and reproductions of his manuscripts may be seen at Swedenborg House, 20, Hart Street, W.C.1. His original manuscripts are preserved in the Royal Swedish Academy of Sciences and in other Swedish libraries.

TUBERCULOUS TRACHEOBRONCHITIS

Cases of tuberculous tracheobronchitis associated with pulmonary tuberculosis have often been reported in the past, and stenotic lesions have been described fully by Eloesser, Haslinger, and Jackson. But the clinical recognition of the earlier manifestations of tuberculous tracheobronchitis and the importance of its occurrence as a complication of parenchymal tuberculosis have been neglected, though the condition is not rare and is of significance in regard to both treatment and prognosis. Three papers have recently been published on this subject, however, from the medical school of the University of Michigan. The attention of the tuberculosis unit had been drawn to a group of patients who developed dyspnoea, wheezing respiration, cyanosis, and intractable cough in the course of pulmonary tuberculosis, these symptoms appearing in some cases when the pulmonary lesions had been regressing satisfactorily. The patients did not respond well to any type of collapse therapy, and 47 per cent. died within a year of the establishment of a diagnosis of tracheobronchial ulceration or stenosis. Bugher, Littig, and Culp¹ have based their pathological study of this condition on 122 necropsies; in every case tuberculosis was the primary cause of death. No less than 41 per cent. of these cases showed lesions in either the trachea or the main bronchi, or both, due to direct contact with sputum containing tubercle bacilli, which gained entrance through the epithelium or through the ducts of the mucous glands, except in some cases in which the main bronchi were affected by direct extension from the peribronchial lesions; this last mechanism was even more important in the intrapulmonary bronchial branches. Tuberculous tracheobronchitis was more frequent in patients with long-standing pulmonary tuberculosis, and although the larynx also was often affected there was no direct relation between the two conditions. Involvement of the tracheobronchial mucosa when it occurred tended to be widespread and most pronounced along the posterior wall. The authors found no definite evidence of healing in any of the ulcers examined, and no presumptive evidence that primary tracheal tuberculosis ever occurs. Samson² describes the characteristic symptoms, stressing particularly the wheezing and rattling, asthma-like attacks in which the difficulty is in inspiration, and paroxysms of coughing. Important physical signs are localized, persistent, audible, and palpable parasternal rhonchi, and the evidence of scattered areas of atelectasis. The diagnosis can usually be made clinically but must be confirmed or refuted by bronchoscopy; gentle manipulation is essential, and the removal of material

¹ *Am. J. med. Sci.*, 1937, 193, 515.

² *J. Thorac. Surg.*, 1937, 6, 561.

rheumatic polyarthritis were treated with serum alone and no relapses occurred. In a second group salicylates were also employed at some time, and in assessing the value of the results special attention was paid to the following: (1) duration of pain and fever; (2) relapse rate; (3) average duration of confinement to bed and to hospital; (4) course of convalescence; and (5) incidence of sequelae. Serum was less efficient than salicylates in securing an afebrile condition, but this was to be expected, and it is interesting that after twenty days all the serum-treated cases were afebrile, whereas about 87 per cent. of untreated cases still showed fever. There were only four cases of true relapse following one course of serum, and the average duration of confinement to bed and hospital, admittedly a fallacious source of information, was forty-two days. The authors wisely refrain from comparing this with the results of other methods of treatment. They believe that the course of convalescence is much more rapid after serum treatment than when salicylates are given; they do not intend at the moment to comment on the incidence of sequelae. There were no untoward results in the patients treated, and while urging that serum therapy should only be carried out in hospital or in equivalent conditions in private practice, they believe that its dangers have been exaggerated. The injections cause a certain amount of local pain, there was an immediate exacerbation of the fever, and about 75 per cent. of the patients developed a mild serum rash. There was one serious reaction: a patient with definite evidence of heart disease developed what may be regarded as a "focal" reaction. The authors suggest that this may be avoided and the serum given even to very ill patients with grave carditis, provided gradually increasing daily doses are used instead of the two ordinary doses in the course. In discussing the effects of the anti-scarlatinal serum it is suggested that some of these may be due to a non-specific action. Three cases of acute rheumatic polyarthritis were given concentrated horse serum containing an equivalent amount of pseudo-globulin. These three cases all showed at least one relapse, so possibly it is the combination of a non-specific element and a specific element in the anti-scarlatinal serum which produces the satisfactory results reported.

CULTURE, COSMETICS, AND MEDICINE

Dr. J. P. Montgomery, in an opening address delivered at the medical school of the Royal Victoria Hospital, Belfast,¹ proved that the humanities are still studied by some members of the medical profession. He called his address "Some Aspects of Medicine and Literature," quoting translations from the Greek anthology made by Dr. J. D. Rolleston and from Martial's epigrams in verse by Sir Raymond Crawford. Dr. Montgomery's survey extends from classical times to those of Clifford Allbutt and William Osler. How little things have changed with the years is shown by the jokes on the *saeva noverca* and the satires on the painting of faces. The Greek anthology tells of a young man who hung a garland on the column at his stepmother's tomb,

thinking that death might have changed her feelings towards him. The column fell and killed him. "Children," says the anthologist, "beware even of the grave of a stepmother." Speaking of the use of cosmetics by the ladies of his day, Lucian says, "Countless drugs are used to doctor their wretched faces. They mix numerous pastes to give a lustre to their disagreeable skins. Some dye their hair like wool, others with colours as bright as the sun at noonday. Those who think that dark hair becomes them best spend their husband's money in scenting themselves with Arabian perfumes. They shamelessly paint their cheeks with bright colours on purpose to show up the excessive pallor of their skin." And so Dr. Montgomery continues his lively paper throughout the ages, giving quotation after quotation with chapter and verse appended until he comes to Dickens and to George Eliot, one of whose characters (Lady Chettam in *Middlemarch*) was assuredly no lover of the highly educated doctor, for she said: "I like a medical man more on a footing with the servants."

THE HEDJAZ PILGRIMAGE

The latest report of the Egyptian Maritime and Quarantine Sanitary Council¹ is the tenth of the series which is annually presented to the Permanent Committee of International Public Health at Paris and to the health authorities of all the countries interested in the pilgrimage to the holy cities of Medina and Mecca. The religious ceremonies, which began on February 20, were attended by about 100,000 worshippers, and there was an increase from 1936 in the number of pilgrims; in the case of those coming from the north it amounted to 60 per cent. The general health was very satisfactory, and the council was able to certify the pilgrimage as having a clean bill of health because of the absence of infectious diseases. As the season for worship advances each year by eleven days it now coincides with a cooler temperature, which accounts for the infrequency of intestinal troubles. In 1936 only a few pilgrims travelled from Jeddah to Medina by air, but this year 105 came by aeroplane, and there are indications that this mode of transport is going to be much more popular in future. Three classes take part in the pilgrimage: (a) Egyptian pilgrims, (b) foreign pilgrims coming via Alexandria, Port Said, and Kantara, and (c) those arriving in steamships by the Suez Canal. All of them have had to submit to variolar vaccination and double inoculations against cholera and typhoid fever. The epidemiology of the countries of origin is studied by the Regional Bureau of Sanitary Inspection for the Near East, and the council is thus made aware of possible sources of infection. By means of international sanitary measures carried out in close co-operation it is not now possible for a pilgrim to obtain a passport unless he is in possession of a medical certificate from recognised doctors stating that he is free of disease. Pilgrims, before being chartered for the voyage, are sub-

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

METHODS OF GIVING BLOOD TRANSFUSIONS

BY

H. F. BREWER, M.D., B.Ch.

In the consideration of this subject a brief note on some of the indications for blood transfusion and on the selection of a donor and the withdrawal of the blood forms a suitable introduction.

Indications for Blood Transfusion

In the anaemia of acute or chronic haemorrhage blood transfusion should be regarded as imperative if the haemoglobin falls to 40 per cent. (Haldane). A drop below this level is dangerous to life: if the haemorrhage has been controlled transfusion will shorten an otherwise long convalescence. In a severe infection (with or without proved septicaemia) transfusion is indicated if the haemoglobin recedes to 65 per cent.: it aids the patient's resistance by combating the anaemia and also by supplying fresh human complement.

Before a severe surgical operation a minimal haemoglobin figure of 70 per cent. should be aimed at. In surgical shock blood transfusion constitutes the best method of increasing blood volume, which has diminished owing to stagnation of blood in the abdominal veins. Lastly, blood transfusion is a valuable therapeutic weapon in the haemorrhagic states and in blood diseases; in the former it is the only specific, though temporary, remedy for haemophilia.

Selection of a Donor

Any adult individual of either sex, with a normal but not necessarily robust bill of health, is suitable. Syphilis and malaria form the two significant transmissible diseases that must be excluded, and allergic individuals are best avoided. Good superficial elbow veins are of practical advantage. It is better that the donor should be of the same blood group as the patient than that Group O subjects should be employed as "universal" donors. In addition to the standard grouping (satisfactory agglutinating serum is now available commercially, from Messrs. Burroughs Wellcome and Co., with a duration of potency of six months) a direct test for compatibility between a drop of the intended donor's blood and the recipient's serum is advised; this provides a check on the original groupings and also excludes the possibility of a subgroup reaction peculiar to the two individuals concerned. Where grouping sera are not available this direct test may alone form the basis of compatibility. It is preferable that a donor should not have had a heavy meal within two hours of being bled; women may donate without ill effect during menstruation providing the latter be normal.

Collection of Blood from Donor

The donor should lie supine on a table, couch, or bed with the selected arm supported on a small firm pad or sandbag. The pneumatic cuff of a sphygmomanometer is adjusted round the upper arm, and the skin over the front of the elbow well cleaned with ether. The veins are rendered full and prominent by inflating the cuff to a

pressure of 75 to 85 mm. of mercury and also by the donor opening and closing his hand on a roller bandage. On selection of a suitable vein (using palpation, if necessary, as well as inspection) a small intradermal injection of 1 to 2 minims of 2 per cent. novocain is given over the site of intended puncture; about two minutes are allowed for this to act. A tiny nick of about 1/8 inch is then made in this anaesthetized area of skin with the point of a scalpel, its length being only slightly greater than the diameter of the small French's needle to be subsequently introduced: it heals rapidly, does not require a stitch, causes no inconvenience, and is not to be confused with a deliberate incision by cutting down on the vein.

Removal of the blood is carried out by a small French's needle (Fig. 1) attached to about twelve inches of stout

ACTUAL SIZE

FIG. 1.—Small French's needle (stainless steel; length of shaft 35 mm.; 7 S.W.G. at mount, tapered to 13 S.W.G. at point; uninterrupted lumen).

rubber tubing of relatively wide bore (internal diameter 5/16 inch) and preferably interrupted by a short glass tubing connexion near the needle to serve as a window. The needle is inserted into the lumen of the distended vein through the small nick in the skin and held firmly in position by the operator: slight adjustment in the depth of insertion ensures the maximum flow of blood, which is aided by the donor opening and closing his hand on a roller bandage about every half-minute. The secret in securing a satisfactory volume of blood from a donor without difficulty is to obtain a good and rapid flow through the needle and tubing throughout the period of collection; liability to clot formation is thus reduced to a minimum.

Sets of rubber tubing with the glass connexions may be sterilized by boiling, or by being wrapped in a towel and put in an autoclave at 120° C. for half an hour. The French's needles, the points of which it is imperative to inspect regularly with a lens and keep well sharpened, are sterilized in spirit or placed in liquid paraffin in a small glass container that is put in a hot oven at 155° C. for one hour. The tubing and attached needle are well rinsed through with sterile normal saline preparatory to use.

The donor's blood is collected in a sterile graduated receptacle containing sodium citrate solution as an anti-coagulant, admixture being ensured by gentle agitation as the blood flows in. Fifty c.cm. of 3.8 per cent. (isotonic) sterile citrate solution is recommended for 600 c.cm. of blood, this amount being increased or decreased according to whether a larger or smaller volume of blood is to be collected. A concentrated sterile solution of sodium citrate—1 gramme in 4 c.cm. of distilled water—is put up by the British Drug Houses Ltd. in small dark-glass ampoules, and keeps well under these conditions: the contents of two of these ampoules added to 50 c.cm. of distilled water or normal saline (the latter resulting in a slightly hypertonic solution) form a satis-

for biopsy is unjustified, since it may lead to a spread of the parenchymatous disease. Four types of lesion can be differentiated: non-ulcerative and non-stenotic, hyperplastic, ulcerative, and fibrostenotic, though in each type the symptoms must be due to some reduction of the bronchial or tracheal lumen. For this reason healing may not necessarily be beneficial, and perhaps this accounts for the fact that "in general the results with regard to the tracheobronchial lesions have been equally poor whether the patient was treated by bed rest only or by collapse therapy, and whether the designated treatment was instituted before or after the appearance of the symptoms of tracheobronchial disease." In only the first type of lesion, therefore, should a patient be given collapse treatment. In the third paper of this series, Barnwell, Littig, and Culp¹ suggest that ulcerative tuberculous tracheobronchitis is a possible and, in fact, probable cause of obstructive atelectasis, the tendency to which is increased by collapse measures. It is also a probable source of the tubercle bacilli found in the sputum of patients with little radiological evidence of pulmonary tuberculosis, and patients with adequate collapse of the lung. It is easy to understand why these lesions are not affected by collapse therapy, which shortens but does not collapse the rigid bronchi; the symptoms may disappear, however, when bronchial obstruction is produced. Collapse therapy is justifiable only when the pulmonary lesion itself is likely to lead to early death. Tuberculous tracheobronchitis is not merely a clinical curiosity, but a syndrome of practical importance in diagnosis, prognosis, and treatment. It may explain the persistence of tubercle bacilli in the sputum in certain cases and the occurrence of atelectasis; and its detection may prevent unnecessary collapse treatment. This is particularly important in the surgical treatment of patients with long-standing disease, in whom these lesions are much more likely to be present.

ELEPHANTIASIS CHIRURGICA

Swelling of the arm after radical amputation of the breast may indicate a recurrence of carcinoma, but this is by no means always the case. With the object of ascertaining the state of and the part played by the axillary vein in these swollen arms, J. R. Veal² of New Orleans has studied twenty cases radiologically after the injection of thorium dioxide into the basilic vein. He finds that post-operative oedema of the arm may be the result of lymphatic obstruction and so correspond to the elephantiasis chirurgica which Halsted described in 1921, or it may be due to constriction or occlusion of the axillary vein, or to both lymphatic and venous obstruction. Obstruction of the lymphatics alone may appear shortly after operation, or may become perceptible months or even years later. The oedema is persistent and brawny, and may be associated with recurrent inflammatory reactions. Venous obstruction produces a different type of swelling. The oedema is soft, pits on pressure, and subsides partially or completely when the arm is elevated; vasography

clearly demonstrates obstruction to the vein, which may be partial or complete as the result either of thrombosis from handling during operation or of pressure by scar tissue. When the arm is abducted the oedema of venous obstruction may diminish or disappear altogether. Lymphatico-venous obstruction is manifested by a pitting oedema which gradually becomes persistent and brawny, and vasography shows venous obstruction. E. A. Devenish and W. H. Graham Jessop³ have found that non-malignant swelling of the arm appears in one out of every six patients after radical mastectomy, and that in one-third of those so affected the enlargement is great enough to cause some distress. They report encouraging results from continuous suspension of the swollen limb, massage, and the subsequent application of a light corset to the affected arm. These two papers indicate the importance of avoiding injury to the axillary vein when performing radical amputation of the breast. Light artery forceps only should be used upon the tributaries of the vein, and these should be tied with the finest ligature material, close to the vein itself but not close enough to constrict its lumen. Care should be taken that the axillary vein is not handled unduly, that a drainage tube is not left in contact with it, and that so far as possible there is an adequate covering of soft parts to prevent constriction by the healing wound. Not so very long ago some surgeons were amputating these distressingly large arms. The modern treatment of carcinoma of the breast and attention to the details elicited from these recent papers should make such mutilation more than ever unnecessary.

THE HALF-YEARLY INDEXES

The usual half-yearly indexes to the *Journal* and to the *Supplement* and *Epitome* have been printed; they will, however, not be issued with all copies of the *Journal* but only to those readers who ask for them. Any member or subscriber who wishes to have one or all of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Secretary, B.M.A. House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this.

The standing commission of the International Red Cross held a meeting at the headquarters of the British Red Cross Society in London on January 24, to determine the agenda and arrangements for the sixteenth International Red Cross Conference, which is to meet in London from June 20 to 24.

Sir David Wilkie will deliver the Mitchell Banks Memorial Lecture on "Chronic Duodenal Ileus" in the Medical School of the University of Liverpool on Thursday, February 3, at 4 p.m.

We regret to announce the death, after a short illness, of Sir Thomas Stanton, K.C.M.G., M.D., who had been Chief Medical Adviser to the Secretary of State for the Colonies since 1926, when that post was first created.

¹ *Amer. Rev. Tuberc.*, 1937, 36, 8.

² *J. Amer. med. Ass.*, 1937, 108, 1236.

³ *Brit. J. Surg.*, 1927, 25, 261.

2. Two pieces of narrow stout-walled tubing which fit the side metal tube openings on the barrel of the syringe. One of these, about ten inches in length, has a weighted perforated sinker at one end; the other, about six inches long, terminates in a male tubing mount which exactly fits into the mount of the metal Jubbé needle.

3. The Jubbé needle, with its well-fitting trocar, the sharp point of which projects just beyond the rounded end of the needle when the mounts of both are in apposition.

The two pieces of rubber tubing are fixed to the side tubes of the syringe, and the perforated sinker at the end of one is placed in sterile saline solution. The syringe and attachments are now filled completely with saline by drawing the latter into the barrel whilst the groove on the plunger is opposite the saline connexion opening, and expressing it through the other piece of tubing after rotating the barrel through 180 degrees to bring the groove opposite the outlet orifice; more saline is then drawn into the syringe, which is left full.

FIG. 4.—Jubbé syringe and needle.

With the same technique as described under Method A, the Jubbé needle, with its projecting trocar, is pushed into a distended anterior elbow vein of the patient through a nick in anaesthetized skin at the site of intended puncture. A rapid efflux of blood from the needle following momentary withdrawal of the trocar indicates a satisfactory insertion. The sphygmomanometer cuff is immediately deflated and the needle fixed to the skin by adhesive strapping, which passes over its shoulder. The trocar is now withdrawn and the male mount on the end of the syringe outlet tubing quickly attached to the needle mount. By pushing down the plunger of the syringe, with the groove opposite the outlet orifice, and injecting saline into the vein it can be seen whether the needle is well inserted. This assured, the tubing end with the perforated sinker is transferred from the saline to the container with the donor's citrated blood. The latter is drawn up into the syringe and injected into the patient in a series of syringefuls by manipulation of the plunger as described. At the termination of the transfusion the needle is withdrawn still attached to the tubing mount and a small dry dressing applied.

The Jubbé syringe components and the needle and trocar may be sterilized in spirit and then rinsed in sterile saline; the pieces of tubing and their fittings may be boiled. In cases of difficulty the recipient's vein may be exposed and

the needle and trocar inserted direct; on withdrawal of the latter the needle may be pushed a short distance up the lumen of the vein so as to anchor it more firmly.

(C) THE KEYNES FLASK METHOD

The equipment (Fig. 5) for this comprises:

1. A thick glass conical flask of about a litre capacity provided with a side tube to which a piece of rubber tubing

FIG. 5.—The Keynes flask and fittings.

carrying a glass air filter and rubber bellows may be attached. The flask is graduated in 100 c.c.m.

2. A rubber bung which closely fits the mouth of the flask and carries a curved glass delivery tube angulated inside the flask so that its lower end, ground slightly obliquely, reaches into the corner. (This part of the delivery tube may with advantage be interrupted at about its middle by two inches of stout-walled rubber tubing.) The portion of the delivery tube outside the flask is curved to end vertically in a tapered extremity, which projects through a small rubber cork about the level of the upper part of the flask neck.

3. A small glass barrel of some 10 c.c.m. capacity which serves as an air lock. The mouth of this accurately fits the cork on the delivery tube, and to its lower end is attached two feet of rubber tubing (3.16-inch bore) terminating in a male Record-fitting mount, with a small glass window interposed immediately above the latter; close to the mount is a bulldog clip.

Blood is collected from the donor direct into citrate solution in the flask; the bung with the delivery tube is then inserted tightly into the mouth (it is wise, before collection of the blood, to confirm the correct position of the end of the delivery tube with the bung inserted), and the air bellows and filter are attached to the side tube. The barrel of the air lock and its tubing are completely filled with normal saline and placed ready in any suitable sterile container.

factory anti-coagulant for 600 c.cm. of blood. The amount of citrate used allows of considerable latitude, but, speaking generally, it should be in the proportion of approximately 0.3 gramme for every 100 c.cm. of blood collected; this is known to err on the safe side, as well as being harmless. It is advisable that the water (including that used in the preparation of normal saline) be rendered as free as possible of dead bacteria and other organic particles by being doubly distilled.

When the requisite volume of blood has been obtained from the donor the sphygmomanometer cuff is deflated and the needle then withdrawn. A dry dressing, to be kept on for forty-eight hours, is all that is required; the application of iodine is to be deprecated, on account of its liability to cause a burn. The donor should lie down for half an hour and be given some light refreshment before leaving. Maximum suggested donations from an average man or woman are 800 c.cm. and 650 c.cm. of blood respectively.

"Cutting down" and exposure of a donor's arm vein by deliberate incision should be quite unnecessary (it is rightly not permissible on the members of the vast majority of voluntary blood transfusion services). It will be seen from the foregoing that the indirect use of citrated blood from the donor is advocated; both to the operator and to the donor it has definite advantages over the direct arm-to-arm technique with whole blood, and the small addition of the anti-coagulant salt has from wide experience proved in no way deleterious to recipient or to transfused blood.

Transfusion of the Patient

The types of transfusion used fall under two headings, depending mainly on the rate of flow and volume of blood given: (I) the ordinary relatively rapid transfusion of quantities up to 800 c.cm. of blood; (II) the slow continuous-drip transfusion of much larger volumes (necessitating two or more donors). For Type I, which has the wider application—although 750 c.cm. of blood raise the actual haemoglobin of an average-sized adult patient by approximately 15 per cent. only—three convenient methods are described, and they are, in order of simplicity:

TYPE I.—(A) FUNNEL GRAVITATION METHOD

The apparatus consists of:

1. A 300-c.cm. capacity graduated cylindrical glass infusion funnel (Fig. 2), attached to the outlet of which is two feet of rubber tubing (3/16-inch bore) ending in a male Record-fitting mount. The funnel and tubing are run through with normal saline, which displaces air in the latter, and about 40 c.cm. of saline are allowed to remain in the funnel by closing a screw clip on the upper part of the tubing. (A Laurie glass drip bulb can be conveniently interposed in the tubing near the funnel, but is not essential.) The mouth of the funnel is lightly plugged with sterile gauze.

2. Two inches of narrow stout-walled tubing (1/8-inch bore) having a female Record-fitting mount at one end and a similar male mount carrying a Record-fitting needle (1.5 mm. diameter or smaller, and 36 mm. length) with a short bevel at the other. A bulldog clip is affixed to the proximal part of the tubing (Fig. 3).

The anterior elbow veins of the patient are rendered full and prominent by inflating a sphygmomanometer cuff placed round the upper arm to about 80 mm. of mercury, the patient co-operating, if possible, by opening and closing his hand on the same side. The arm is fully extended with adequate support, in a good light.

The skin at the site of puncture of a chosen vein is anaesthetized by a small intradermal injection of 2 per cent. novocain and a small nick is made in it, as described for bleeding a donor. The Record needle, attached to the short piece of narrow stout-walled tubing already described, is pushed through the skin nick into the vein;

FIG. 2.—Cylindrical glass infusion funnel.

its point is indicated to be in a satisfactory position in the lumen of the latter by a brisk flow of blood from the female mount at the end of the tubing on momentarily releasing the bulldog clip; slight adjustment in the depth of the needle may be necessary to obtain this. The sphygmomanometer cuff is then immediately deflated and the needle fixed firmly in position with a

FIG. 3.—Needle tubing connexion.

piece of adhesive strapping passing over the mount and the proximal part of the shaft. Warning is given to the patient not to move the arm. Firm connexion is now made, by adjusting the mounts, between the needle tubing and that attached to the funnel; the bulldog clip on the former is removed, the screw clip on the latter opened, and with the funnel held above the patient's level saline will flow into the vein. Before the saline is exhausted the donor's blood at 37° C. is added to the funnel and replenished from time to time when the level falls to about the 50-c.cm. mark. The rate of flow can be controlled by the screw clip or by raising or lowering the funnel in relation to the patient. At the end of the transfusion the bulldog clip is replaced on the needle tubing, the needle withdrawn, and a simple dry dressing applied.

With the exception of the needle the whole of this simple apparatus may be sterilized by boiling or in an autoclave. In a patient who is very restless, or in whom the veins are small and difficult, the Record-fitting mount at the end of the funnel tubing may be inserted into two inches of narrow tubing carrying a small glass Keynes cannula; the latter is then tied into a suitably exposed vein (see Method C below), after displacement of the air, by running through some of the saline from the funnel.

(B) JURE SYRINGE METHOD

The apparatus (Fig. 4) consists of:

1. The special syringe. This comprises a glass barrel with two side metal tube openings, and a metal plunger with a longitudinal groove which does not quite reach its base. The components are fitted together by means of a screw cap; the capacity of the syringe may be either 5 or 10 c.cm. With the plunger pushed right down and the longitudinal groove opposite one of the side openings withdrawal will suck in fluid only by way of the latter; if the plunger be now rotated through 180 degrees, so that the groove is directly opposite the other side opening, pushing it down will empty the syringe through this orifice. The principle depends on unmasking one of the barrel openings with the groove of the piston while sealing the other with the convexity.

and displace air in the pressure tubing and terminal cannula. A saline level with air lock is produced in the drip bulb by momentarily inverting it. The screw clip is then almost closed and the saline flow in the bulb reduced to a slow drip; this and the corresponding flow from the end of the cannula is stopped by occluding the pressure tubing, a short distance proximal to the latter, by a strong bulldog clip. Under local anaesthesia a vein in the forearm, antecubital fossa, or the internal saphenous just above the malleolus is exposed and ligatured; the cannula is introduced up to the shoulder of its bend and tied into the vein just distal to this—using a technique

FIG. 6.—Continuous-drip transfusion apparatus (Marriott and Kekwick).

on the lines previously described for a Keynes cannula. Removal of the bulldog clip should now allow the flow of saline as observed in the drip bulb to begin again. The skin edges are sutured above and below the point where the cannula enters the vein. The barrel of the cannula and the distal eighteen inches of tubing, loosely looped, are securely fixed with strips of adhesive strapping to the surface of the limb, covered with sterile gauze and wool, and bandaged lightly. The oxygen is now turned on at a rate of 80 to 100 bubbles per minute, as judged by its flow, through the remaining saline in the container (a Woulfe's bottle, half full of water, through which the oxygen passes, can with advantage be interposed between the cylinder and the suspended container). The rubber bung is temporarily removed and sterile citrated compatible blood up to two pints introduced. The blood used in the container must all be of one group, preferably the same group as the patient; provided care is exercised in its collection from the donors into the citrate solution there is no need to strain it. Forty drops per minute—that is, a pint in four hours—is a satisfactory rate of drip for which to adjust the screw clip, but a faster or slightly slower delivery can be utilized, according to indications.

The frequent attention of a nurse is necessary to control by the screw clip any fluctuation in the rate of drip; it is essential that this be not allowed to slow up unduly or cease for even a short interval. In addition the oxygen flow must be maintained but over-frothing controlled; prevention of red cell sedimentation is also assisted by an occasional manual agitation of the container. More blood is added to the latter when its contents have dropped to about 150 c.cm. The amount necessary to bring the haemoglobin percentage up to a given level can be assessed on the knowledge that 750 c.cm. of blood in an average-sized adult will raise the haemoglobin about 15 per cent.; in the presence of bleeding more is required. A haemoglobin estimation carried out from time to time during the course of the transfusion is helpful.

The donors are conveniently bled in pairs and their blood stored in a cool place: it is shaken up gently and brought to body heat before addition to the reservoir. The advantage of using a forearm vein in the patient is that some mobility of the limb can be allowed. With an antecubital or the internal saphenous vein (thrombosis is less liable with the former) insertion of the larger-size cannula is possible and advantageous, but the limb should then be immobilized with a small splint or sandbags. At the end of the transfusion the screw clip is closed and the cannula removed under local anaesthesia; the vein is then ligatured, if necessary, on the proximal side and the skin edges resutured. All the apparatus used, except the oxygen cylinder, is sterilized by autoclaving in a dressing drum.

In concluding this article it must be emphasized that the methods of blood transfusion are legion: those described above represent a few proved techniques by means of which this valuable remedy may be employed in general practice.

The apparatus of the various techniques considered is obtainable from Messrs. Willen Bros., New Cavendish Street, W.I., who have kindly provided the drawings.

S. Lomholt (*Ugeskr. Laeg.*, 1937) bases his belief that gonorrhoea is on the increase among women in Copenhagen on the returns of the venereal disease dispensaries which provide free treatment under the auspices of the municipal authorities. These dispensaries, which deal with at least two-thirds and possibly three-quarters of all the recent cases of venereal disease in Copenhagen, make detailed monthly returns. The figures for 1931 showed 1,207 male cases and 312 female cases. The corresponding figures for 1936 were 1,647 and 631 respectively. It will thus be seen that the figures for female patients have been more than doubled in five years, whereas the rise in the number of male cases has been much less marked. After discussing possible sources of error which might exaggerate these variations, the author admits that the true rise in the number of male cases may be comparatively small. But the enormous rise in the number of female cases is not to be gainsaid, and he attributes it to the growing alacrity with which young women at the present time indulge in premarital and extramarital sexual relations. It is particularly between the ages of 16 and 18 that this movement has been most marked. The author points out that at least 50 per cent. of all cases of inflammation of the uterine appendages are gonorrhoeal, and that the annual reports of the five municipal surgical hospitals in Copenhagen for 1935 and 1936 have shown that more than 500 cases of salpingitis were treated in them. Every year between 1,000 and 1,200 young women contract gonorrhoea in Copenhagen, and as the prospect of their early and complete cure is problematic, the outlook with regard to stamping out this disease is very poor in the absence of any reliable specific drug or remedy.

With a similar Record needle and short rubber tubing attachment and mounts as described under Method A, the needle is inserted in an anterior elbow vein of the patient by an identical technique and strapped in position. The mount on the end of the air-lock tubing is now fitted to that on the needle tubing and the clip on the latter removed. On releasing the clip on the tubing of the air lock, held above the patient's arm, satisfactory insertion of the needle will be indicated by a slight drop in the saline level in the barrel. The mouth of the latter is then fixed securely to the rubber cork on the end of the delivery tube and the clip on the air-lock tubing removed.

Positive pressure being produced inside the flask with the bellows, citrated blood rises in the delivery tube, pushing the air in the latter into the barrel of the air lock, from which a corresponding volume of saline passes into the recipient's circulation. As the blood begins to flow into the air lock the remainder of the saline solution is driven on into the patient's circulation, to be followed by the blood, an upper level of which is present in the barrel. The rate of flow, as judged by the efflux from the delivery-tube nozzle in the air lock, is easily controlled by variation in the positive pressure produced by the bellows. When the flask is almost empty it is held tilted towards the end of the delivery tube inside so as to aid exhaustion; as soon as air rises in the delivery tube and displaces the blood level in the air lock the tubing on the latter is clipped and the needle withdrawn from the patient's vein. If preferred a Jubbé needle and trocar, with a corresponding mount at the end of the air-lock tubing, may be employed for the venepuncture.

When the veins are small or inaccessible a Keynes glass cannula with a short narrow tubing connexion tied on to the air-lock tubing mount and full of saline can be used. Omitting application of a sphygmomanometer cuff, except for preparatory localization, the vein is cut down on and exposed for about three-quarters of an inch under local anaesthesia (2 per cent. novocain with a small addition—1 minim to each drachm—of liq. adrenalin. hydrochlor. 1 in 1,000, as a haemostatic). With a blunt aneurysm needle three separate lengths of No. 0 catgut (or No. 0 silk) are passed under the vein, and the latter tied distally with one of these. Just proximal to this ligature a transverse cut (not complete division) is made with a sharp pair of iris scissors in the wall of the vein, held in forceps; the end of the cannula is introduced into the lumen of the vein through this opening and tied in position around the slight constriction on its neck with one of the lengths of catgut already in position. At the termination of the transfusion the ligature around the cannula is cut and removed; an assistant then withdraws the latter as the vein is tied above the opening in its lumen with the remaining lengths of catgut. The edges of the skin incision are sutured with horsehair.

Sterilization of the apparatus (omitting the bellows) is best carried out in the autoclave after wrapping in towels; the needles are placed in spirit.

All the above methods—A, B, and C—will give satisfactory results. The infusion-funnel gravitation technique involves the use of very simple apparatus; but it has not the reserve of pressure sometimes necessary to overcome venospasm in a collapsed patient. The Jubbé apparatus is compact, easily sterilizable, reliable, but expensive. The Keynes apparatus is very satisfactory in the hands of those well acquainted with their own apparatus: the various connexions and the glass and rubber tubing need frequent supervision and overhaul.

Whatever method is employed sterility throughout is imperative and all apparatus must be scrupulously clean; both for donor and recipient the employment of well-sharpened needles in rendering the task of the operator easier cannot be too strongly emphasized. The blood should not be transfused into the patient too rapidly—a pint in half an hour is a reasonable rate. Lastly, in this relatively rapid type of transfusion care should be taken to give the blood at as near body temperature as possible; strict attention to this also eliminates mild reactions in the patient resulting from minor degrees of cold agglutination. In Method A warm blood is added to the infusion funnel about 150 c.cm. at a time. In B and C the blood receptacle and the Keynes flask respectively are stood in water at 37° C. during transfusion. In infants and young children, in whom the antecubital veins are very small, the introduction of a needle or fine glass Keynes cannula into the internal saphenous vein, exposed near the ankle, is recommended.

Untoward post-transfusion (non-haemolytic) reaction in a patient is best controlled by the hypodermic injection of morphine tartrate 1/6 to 1/3 grain, and adrenaline hydrochloride (1 in 1,000) 7½ to 15 minims, the dose varying according to the size of the patient and the degree of reaction.

TYPE II

The slow continuous-drip transfusion, introduced by Marriott and Kekwick in 1935, has proved very valuable in raising the haemoglobin percentage of a severely anaemic patient to a high level by giving such amounts as one to four litres over twelve to forty-eight hours. It is especially applicable in severe gastric or duodenal haemorrhage: besides markedly improving the general condition of the patient treated medically, it renders surgical intervention much safer should this prove necessary.

The apparatus (Fig. 6), based on the original description, comprises:

1. A glass container of about four-pint capacity fitted with rubber bung carrying two short pieces of bent glass tubing. To the inner end of one of these a piece of rubber tubing is attached reaching to the bottom of the container; through it filtered oxygen can be bubbled, so preventing red cell sedimentation. The other piece of glass tubing, furnished with a filter, is an exit for the oxygen. The container is encircled by a metal hanger for suspension.

2. A long Laurie glass drip bulb,* fitted to the outlet on the container by about four inches of rubber tubing on which is an adjustable screw clip.

3. Six or seven feet of fine pressure tubing (5 mm. external diameter) connected to the lower end of the drip bulb via a glass adapter and terminating in a special Marriott glass cannula (supplied in three sizes). The right-angled bend near the bulbous tip of the latter enables it to be tied into a vein without causing kinking.

4. An oxygen cylinder with pressure regulator and fine adjustment tap, connected to the inlet glass tubing on the rubber bung of the glass container by rubber tubing interrupted with two or three filters.

About 100 c.cm. of sterile normal saline are poured into the glass container, suspended three to four feet above the patient; by opening the screw clip wide some of this saline is allowed to run through the drip bulb

* The provision of a short side tube towards the upper end of the drip bulb is a recent improvement introduced by the originators of this technique. The side tube terminates in a short piece of rubber tubing closed by a metal clip. By means of this lateral airway the level of the blood in the bulb is easily adjusted during the course of the transfusion. Further, by applying to it a syringe containing air, and closing the screw clip on the tubing above, the pressure in the bulb can be momentarily raised to expel any small clot obstructing the terminal cannula.

Nova et Vetera

THE COLLEGE OF PHYSICIANS OF PHILADELPHIA, 1787-1937

On May 14-15, 1937, the fourth oldest medical society in North America celebrated the 150th anniversary of its foundation. John Redman was the first president, and the famous Benjamin Rush, who had signed the American Declaration of Independence in 1783, delivered on February 6, 1787, a discourse on the objects of the College. In the full report of the celebration now published, Rush's discourse is described as "a Declaration of Independence of the American Physician." The Philadelphia College of Physicians started with twenty-four Fellows, and now has 680. The original twenty-four founders were divided into twelve seniors and twelve juniors, and among the former was John Morgan the elder (1735-89), the father of medical schools in North America, for he founded in 1765 the medical department of the University of Pennsylvania, the first to be established in the British colonies. The College of Physicians of Philadelphia, though originally modelled on the Royal College of Physicians of London, is now in some respects more like the Royal Society of Medicine than the London College, for it has five sections—of ophthalmology, otolaryngology, general medicine, medical history, and public health, preventive, and industrial medicine—each with its own chairman, "clerk," and executive committee, and meets every month from October to April. The College does not confer diplomas to practise, and has many surgeons among its Fellows, the word "physicians" meaning medical men, and not being restricted to those sometimes called "internists": thus Professor D. Riesman, in his account of the College's library, refers to Sir James Paget, the surgeon, elected a Fellow in 1874, as "one of the most distinguished British physicians." On the other hand, the Philadelphia College has its four censors: and its *Transactions*, which began in 1793, resembled the *Medical Transactions* (1769-1820) of the London College in that a number of the articles in both were in the form of letters addressed to, and communicated by, Benjamin Rush and William Heberden the elder respectively, who were the active spirits in connexion with the *Transactions* of the two Colleges.

The library of the College of Physicians of Philadelphia is an outstanding feature. At its centenary in 1887 it contained 38,000 volumes; now the number has reached 178,000. It is particularly rich in incunabula, books printed in what has been called the cradle period of the printer's art—namely, before 1500. Of these it possesses 415 out of the 600 known medical volumes, being second to the Army Medical Library at Washington, which has 450. In 1876 the College received 80 out of the current 280 medical periodicals: now it takes about 1,200 out of the 1,800 in existence.

A number of addresses were delivered at the recent celebration: Sir Henry Dale, the delegate of the Royal Society, speaking on medicine as an experimental science, recalled the solemn warning given him by the late Samuel Gee to forget all the physiology he had learnt, "as it was an experimental science and had nothing to do with medicine, which was still an empirical art": adding, "Some day we hope that medicine, too, may become an experimental science, but that day is not yet with us." Sir Henry rightly believes that the day has now come. Other addresses were on the future of medical research, by the Hon. Roland S. Morris, president of the American Philosophical Society, which has long been closely associated with the College; on the transformation of medicine by public health development, by Professor Hans Zinsser, who considered the part that such institutions will play

in the future: on the question why academies were founded, by Professor H. E. Sigerist; on the College, by Dr. G. P. Muller, its president; and on the College from 1887 to 1925, by Dr. F. R. Packard, an ex-president and editor of the *Annals of Medical History*.

ANNALS OF MEDICAL HISTORY

The final instalment of the volume for 1937 contains four main articles, a smaller number than usual, but of very considerable interest and generously illustrated. Harold Wellington Jones, librarian of the Army Medical Library, better known by its former title, the Library of the Office of the Surgeon-General of the United States Army, contributes from his splendid store "A Portrait Gallery of Physicians." This is accompanied by twenty-five illustrations, including fine reproductions of the paintings of Surgeon-General William C. Gorgas and Dr. Robert Fletcher. Many of the portraits are of former Surgeons-General with old-fashioned beards, but there are also pictures of John Hunter and Bichat. Dr. Francis R. Packard gives an account of William Cheselden and some of his contemporaries and their American pupils, such as John Jones, who was Benjamin Franklin's doctor and the best-known American surgeon before Philip Syng Physick. A kindred subject, the "Rise of British Surgery in the Eighteenth Century," by Dr. Fernick Besterman, also well illustrated, necessarily covers some of the same ground, but in wider detail, and reproduces Holbein's famous picture—in the Barber-Surgeons' Hall—of Thomas Vicary receiving the Company's Charter from Henry VIII, of which there is a fine replica in the Royal College of Surgeons of England.

Dr. Gilbert Roy Owen gives an interesting account of the famous case of Lady Anne Conway, "the most learned of the female metaphysical writers of England," for whose "terrific recurrent cephalalgia" the advice of an imposing array of consultants, including Harvey, Willis, Mayernz, Robert Boyle, and van Helmont, was in vain. In a sympathetic editorial the life and services of the late Paul Hoerber, who brought out the nineteen volumes of the *Annals of Medical History*, are sketched by Dr. Packard.

A FLORENCE NIGHTINGALE COLLECTION

In the catalogue of Sir William Osler's library Florence Nightingale rightly occupies a place in its select "Bibliotheca Prima," for it was under her that, to quote Osler in one of the attacks of race-mania, the nursing profession, until then unsettled and ill defined, took its modern position. Many of her manuscripts, letters, and other memorabilia are scattered throughout the world, and to catalogue this material would be a pious task. The School of Nursing of the Presbyterian Hospital in New York has done well to bring out a printed catalogue of its Nightingale Collection, which is splendidly displayed in a special room at the nurses' residence. Each class, after studying the history of nursing—a subject taken much more seriously in America than in Britain—contributes something to this museum. The letters, some of which are transcribed, range in date from 1854—in 1855 Florence Nightingale had taken up her first post as superintendent of the "Sick Governesses' Home" in Harley Street—to 1896, but some are undated. In a letter written from Scutari in 1856 she describes as "a mass of mischief and rubbish" the books sent from England for the soldiers—odd volumes of novels, registers, and treatises on midwifery.

Annals of Medical History. New Series, Volume 9, Number 6, 1937. Edited by Francis R. Packard, M.D. (pp. 517-544). Illustrated. Volume of six numbers, 22 (1937) single numbers, 17s. 6d. New York: Paul B. Hoeber. London: Baillière, Tindall and Cox.

THE SLOUGH SOCIAL CENTRE

[FROM A CORRESPONDENT].

The Slough Social Centre, which was opened last year and was recently visited by the King and Queen, is an ambitious effort to meet the social needs of a rapidly growing industrial area. It can fairly be ranked as a pioneer experiment, for although there are community centres on many of the new housing estates, none is conceived upon such bold lines or attracts so large a proportion of the population at its doors. On any evening of the week 1,500 persons are assembled at the Centre. Slough is described even in current gazetteers as a market town with a population of 16,000, but in recent years it has broken its bounds and multiplied its population more than threefold. On what used to be open country within sight of Windsor Castle there are now on every side factories and working-class houses. There is talk already of Slough as a second Manchester by 1960. Eleven thousand people from the distressed areas alone have migrated to Slough, and we are told that the Welsh accent is heard here as frequently as in the Rhondda Valley.

The Centre, which has been built and equipped at a cost of £52,000, itself resembles a modern factory building, except that there is rather more decorativeness about its 600 feet of frontage and its six large welcoming doors. The building consists of three blocks, one for the junior section, one for the senior, and a central one comprising a great hall, seating 1,000 people, with stage and dance floor. Every kind of social, cultural, and recreational facility is provided. There are three gymnasiums, a swimming bath, with artificial sun-ray equipment for use in the winter, abundant facilities for indoor and outdoor games, also for music, lectures, and discussions, and workshops for the teaching of handicrafts. A canteen has been installed where refreshments can be procured at the lowest economic cost. The Centre is still in course of development, and it is hoped to add running and cycle tracks and athletic grounds—altogether one hundred acres of playing fields.

Provision for Physical Education

Unlike the Peckham Health Centre, which it resembles in much of its layout and activity, Slough is not primarily a health organization. One of its important purposes, however, is to provide physical education. It has classes for this purpose, although the word "class" is not stressed lest it should suggest something irksome. The principal gymnasium, equipped with shower baths, is used by men on two nights a week, and by women on two nights, and certain other events, such as boxing and fencing (the latter for both men and women), fill up the rest of the time. The exercises are carefully graded, and skilled instruction is given. In the junior section—meaning by "junior" the ages 13 to 18—a system, though not a compulsory one, of medical inspection has been set up. It is considered desirable for the purposes of the Centre that it should be known whether the young person is fit for the exercises provided, and it is hoped that the habit of seeking medical inspection will become a routine.

Advisory Medical Service

The Centre has two voluntary medical officers who live in the district. Their province is only to advise; no treatment is given, but it is considered that the facility for inspection may furnish a desirable link between skilled medical supervision and national health insurance. One of the officers is already familiar to the lads as a school doctor; the other, who deals with the girls, is the only woman practitioner in Slough. If a boy or girl is found to be in need of medical treatment the fact is conveyed to the parents with a view to bringing him or her under the care of the general practitioner. Should the parents be remiss in this respect there are other ways of ensuring

that medical attention is afforded. Both medical officers are themselves members of the Centre, and moving among the nightly groups at the various classes and recreations, if they see a lad or a girl who appears to need attention, they put in a timely word. The medical card in the junior section is a very complete document. It includes a space for personal and family history, home conditions, character, athletics, hobbies, physical measurements, conditions as to cleanliness, the state of the teeth and tonsils, heart and lungs, blood pressure; any such abnormalities as varicose veins, flat-foot, or spinal curvature are noted, and there is space on the card for the name and address of the insurance practitioner.

Infant Welfare and Nursery School

For still younger members of the community there is a flourishing infant welfare centre, where about 150 infants are seen every week by a doctor who is a medical officer of the Buckinghamshire County Council, and in a detached building on the site, put up by the county council at a cost of £4,000, a nursery school has been established for children of from 2 to 5 years, which is already taxed to its capacity of 80. The children receive three meals a day, and during the first term not one child failed to grow and put on weight. In the selection of children for the nursery school certain priorities are observed. The idea is to take in children who have no father and whose mother goes out to work, but preference is given to the not infrequent cases where the toddler in a large family is apt to be neglected, and the not less important case of the only child who in the nursery school may be delivered from some of the misfortunes of that situation and learn its first lesson in sharing.

Finance and Administration

The idea of the Centre came from the employers (a valuable lead being given by Mr. A. N. Mobbs, chairman of Slough Estates Ltd.), and was seconded by voluntary associations and public bodies. Buckinghamshire County Council made a contribution to the total cost, and its education committee is contributing £1,500 a year to the support of the junior section. The senior section is self-supporting. The members of the council of the Centre include Slough industrialists and representatives of the county and urban district councils. An advisory committee consists of representatives of such bodies as the National Council for Social Service and the Industrial Welfare Society, with advisers from the Board of Education and the Ministry of Labour, also the medical officer of health and education officer for the county. The junior section is administered by a committee of local people, with representatives of the churches and of youth organizations. The administrative staff has at its head in Mr. A. T. Carr a very competent warden. One of the chief values of the Centre is that it brings about a mixing of the classes, those who can give socially as well as those who receive; although it does not lay the same stress as Peckham on the family unit, it is for the whole family, including the woman stale from domestic work and the adolescent fresh from school. It also represents a happy combination of voluntary and local authority enterprise.

Dr. L. Haden Guest, M.P., secretary of the Leverhulme Research Fellowships, announces that applications are invited for fellowships or grants in aid of research. They are intended for senior workers who are prevented from carrying out research by routine duties or pressure of other work. Any subject which may add to human knowledge may be proposed for a fellowship, but preference is given to subjects in which other provision for research is inadequate. The amount granted will depend on the nature of the research and the circumstances of the applicant. Forms of application, returnable by March 1 at latest, may be had from Dr. Haden Guest, Union House, St. Martin's-le-Grand, E.C.1.

be preferable in non-malignant gynaecological conditions, as the effect of radium could only be quite local and the treatment of the conditions under discussion was so frequently a matter of treating organs other than the uterus.

Value of Radiotherapy

Mr. LEONARD PHILLIPS gave an elaborate analysis of the literature on the subject which had appeared since a discussion at the Royal Society of Medicine in 1933, chiefly concerning the indications for operation or irradiation, and the respective advantages of the methods, in menopausal menorrhagia and fibroids. The advantages of radiotherapy over operation included the lessened morbidity, the shorter recovery time and period of hospitalization, and the lower cost. With radium there was a very slight mortality, and with x rays none. Radium had a certain definite morbidity, due generally to burns, but occasionally other complications, such as broad ligament abscess, phlebitis, pain in the groin, rectal ulcer, and intestinal obstruction, had been noted. The morbidity of surgery, of course, was greater. A moot point was whether radium acted on the ovaries or on the endometrium; if it acted on the ovaries then there was no advantage in using it in preference to x rays; indeed there was a disadvantage, because of the many local sequelae of an unpleasant nature following radium treatment. Forsdike stated that with experimental animals the effect was almost entirely on the endometrium: on the other hand, Clarke and Norris had found that late effects on the ovary were destructive of the follicles. It was a matter on which more experimental evidence was necessary. Undoubtedly x rays acted entirely on the ovaries, but it was difficult to determine whether radium did so.

A great difference of opinion was evident in literature on the question as to what cases (of menopausal menorrhagia and fibroids) should be handed over to the operating gynaecologist and what should be reserved for treatment by irradiation. At one extreme was Bécélère, who declared that fibroids always constituted an indication for x-ray therapy. The general conclusion to be drawn was that the cases might be divided into three groups: those in which surgery was obviously indicated, those in which radiology was obviously indicated, and those in which the indication was doubtful. On the question of the possibility of cancer production by irradiation, Essen-Möller of the Lund Clinic recorded six cases of cancer developing after radium treatment.

Mr. Phillips also analysed 165 cases in which subcastration doses had been given for severe haemorrhage in young women. He thought it was now established that there was no danger to future labours from cervical scarring; Murphy's series of over 400 cases had shown this. There was also apparently no danger of deformity or abnormality of the foetus from preconceptional irradiation. In 600 cases Murphy found abnormality in only a negligible percentage (1.1). With regard to the effect of stimulating ovarian and pituitary irradiation for amenorrhoea, menorrhagia, dysmenorrhoea, sterility, and other conditions, an analysis of 100 cases from the Hospital for Women, Soho Square, was disappointing. In about 50 per cent. radiation treatment was a failure; in 40 per cent. there was slight improvement, and the remainder might be described as cures. The only consistent beneficial effect was an improvement in the attendant headache.

Methods of Treatment Compared

Dr. LOUISA MARTINDALE analysed her treatment of 878 cases of metropathia haemorrhagica, fibrosis uteri, and fibromyomata from 1914 to 1937. Surgical operation (hysterectomy or myomectomy) had been carried out in 471 cases with a mortality rate of 1.9 per cent., radiation treatment in 407 cases (deep x-ray therapy in 298 and radium in 109) with no mortality. Many clinics in which

both methods were practised showed a much lower proportion of cases treated by surgery. Gauss of Würzburg, for example, had treated surgically only 15 per cent. of 1,048 cases. Many people thought that the menopausal symptoms were severe in cases treated by x rays, but the results of a questionnaire sent to her patients with regard to these symptoms did not bear this out. The advantages of x-ray over radium therapy were that x-ray treatment was attended by practically no morbidity and the treatment was very short. There was no evidence that preconception radiation was harmful to the child. An advantage of radium over x-ray therapy was the mere rapid cessation of haemorrhage.

Mr. MALCOLM DONALDSON said that it had still to be proved whether small doses of radiation had any effect on subsequent pregnancies. Until it had been established that this was not the case irradiation should not be carried out on patients under 40. In cases of fibroids radiotherapy should only be used when the fibroid was not larger than at most a full-size foetal head. It was difficult with a large fibroid to be certain of excluding any inflammatory condition in the pelvis. Large fibroids were likely also to undergo sarcomatous changes, and the dose given to create an artificial menopause was not sufficient to prevent this. Before undertaking radiotherapy it was essential to explore the uterus, and if the uterus was to be explored the simplest procedure was to put in some radium at the same time.

Mr. CARNAC RIVETT said that most of the speakers had put forward certain contraindications to the radiotherapeutic treatment of fibroids, and if all of them were accepted it seemed as if the only fibroids suitable for x-ray treatment were those which gave rise to no symptoms at all! He went on to refer to the great severity of the comparatively rare cases of menorrhagia in women of 18 to 20; he knew of one patient who had died from haemorrhage in simple profuse menorrhagia. Mr. RALPH PHILLIPS objected to the term used by Mr. Leonard Phillips—"sub-castration dose." It was a castration dose, but the function recovered: the ovarian function could not be permanently destroyed, certainly not in young women. The radiotherapy of non-malignant disorders in general had suffered from the fact that the cancer problem dominated the mind of the radiotherapist, and while he knew what he was trying to do in cancer he had no idea of what he was aiming at in non-malignant conditions. The fundamental basis of radiotherapy in non-malignant conditions was destruction of the leucocytes and radiosensitive cells of that type. The effect of radiation was invariably destructive even in small doses.

Professor MILES PHILLIPS, president of the Section of Obstetrics and Gynaecology, who wound up the discussion, said that as a practising gynaecologist he had learned more than he had expected from what had been said. He mentioned the effect of stimulation of the ovary in a woman of 29 who had not menstruated for ten years: after radiation menstruation began again, and later she had two children. With regard to the effect of radium in stopping menstruation, he thought this depended upon the time in the menstrual cycle when radium was inserted. If it was inserted in the early stages it was possible to tell the patient with precision that she would not have another period; if in the later stages, another period was likely.

WATER POLLUTION AND TRADE EFFLUENTS

Dr. A. PARKER of the Water Pollution Research Board of the Department of Industrial and Scientific Research, in a paper read before a joint meeting of the Institutions of Civil Engineers and Chemical Engineers, said that the public water supply undertakings in Great Britain distributed from 1,000 million to 1,500 million gallons of water per day to a population of 35 to 40 millions. This quantity was used mainly for domestic purposes, though some is used for industrial purposes.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

Presiding at the annual meeting of the Court of Governors of the London School of Hygiene and Tropical Medicine on January 24 the PRIME MINISTER paid tribute to his brother, the late Sir Austen Chamberlain, whom he succeeds as chairman.

"Even the most inexperienced of statesmen," he said, "would hesitate before taking on fresh liabilities, however nominal, just at the moment when he became Prime Minister. The circumstances in this case were, however, exceptional. In considering the request that was made to me I had in mind the long connexion between my family and this School, the intense interest taken by my father in the study of tropical medicine, my own much more modest share in public health in this country, and, of course, the fact that my brother was for five years your chairman. I think that what finally weighed with me was my sense that your invitation to me to fill my brother's place was perhaps the greatest and sincerest tribute you could pay him."

A Balanced Budget

Continuing, the Prime Minister said he was glad to see that the School had a balanced budget. If they analysed the income they would find that the principal part consisted of the grant from the Exchequer of £40,000. They had £7,000 from students' fees and about the same amount from endowment funds. This meant that the remaining £12,000 of their £66,000 expenditure had to be made up by voluntary contributions and donations. They must expect that if anything happened to give a setback to the present comparatively prosperous condition of the country they might have to face some diminution of voluntary contributions. The existing reserve fund for building and equipment, which was a little over £4,000, was not really adequate, and the moral was that the School was in need of further endowment. One of the most useful forms was the endowment of chairs or readerships. For a professorship £50,000 was required and for a readership £35,000.

The Work of the School

In commending the annual report to the Court of Governors Mr. Chamberlain said that it demonstrated the wide range of the work of the School, the imagination of those responsible for its affairs, and the practical importance of its teaching and research for the public health. The staff had been active both in the laboratories at home and over-seas. He was glad to hear that since the publication of the report a new branch had been instituted through the Ross Institute in Ceylon, in which the School and the Ross Institute would co-operate with a committee of estate proprietors in securing malaria control and other health measures on a group of estates in that country. Mention was made in the report of the conference held in the School in September by the Central Council for Health Education, at which he had himself presided. He was very glad that this School should be associated with efforts to secure a wider appreciation and a fuller use of the public health services, for it was already associated with those services in a variety of ways: in the training of future medical officers of health and in the work carried out on behalf of various Government departments. On behalf of the Ministry of Health, for instance, the School was carrying out researches such as the investigation of problems relating to standards of purity in the milk supply; was supervising the treatment of certain nervous disorders by means of induced malaria; and, in Professor Greenwood's department, was carrying out statistical analyses for the medical intelligence division of the Ministry.

The Dean of the School, Professor W. W. JAMESON, gave an account of the work of the School during the year, and at the conclusion of the meeting it was announced that Mr. Chamberlain had agreed to become chairman of the standing committee of the Ross Institute of Tropical Hygiene.

Reports of Societies

RADIOTHERAPY OF NON-MALIGNANT GYNAECOLOGICAL DISORDERS

At a meeting of the Sections of Radiology and of Obstetrics and Gynaecology of the Royal Society of Medicine on January 21, Dr. R. E. ROBERTS presiding, the radiotherapy of non-malignant gynaecological disorders was discussed.

Uterine Lesions

Dr. W. M. LEVITT said that the principal non-malignant abnormal conditions of the uterus that might be treated by radiotherapy were uterine fibroids, endometriosis, and certain chronic inflammatory conditions. The mode of action on fibroids was largely through the ovaries, and treatment meant sterilization of the patient. Irradiation was therefore contraindicated during the child-bearing age, at all events before the age of 40. He took the age of 40 as a convenient dividing line, but the general impression given by the patient of what might be termed her physiological or ovarian age was a reliable guide. At or near the menopause irradiation became the treatment of choice, except in cases in which the fibroid was of excessive size and causing pressure symptoms, or in which there were acute complications or clinical evidence of fibroid degeneration. X rays had the advantage over radium of greater ease of application and of avoidance of an anaesthetic and of any uterine procedure. Radium had the added disadvantage that a very large dose had to be applied to the uterine mucosa to secure sterilization. In the treatment of endometriosis irradiation was effective, but here again the consensus of opinion seemed to be that it must necessitate sterilization. His own experience of radiation therapy in this condition was limited to one case, in which the result supported this view. If that was so it was obvious that where the lesion could be excised without at the same time producing surgical sterilization surgery was to be preferred to x-ray therapy.

After a brief reference to the treatment of tuberculous and gonococcal conditions by radiotherapy—a treatment practised abroad, especially in Germany, but very little in this country—Dr. Levitt dealt with the possibility of the production of malignant disease by x-ray treatment. The answer to such a suggestion was that malignant disease could only be produced by small doses of x rays repeated over a period of years. Such conditions were only fulfilled in radiologists or in those handling x rays or radium for experimental or trade purposes.

Extra-uterine Lesions

Dr. J. F. BROMLEY said that menopausal symptoms, either natural or induced, were connected with an increased pituitary output, and it was generally agreed that relief could be obtained from appropriate irradiation. The regular occurrence of really incapacitating headaches, for example, might be due to the encroachment of the pituitary in a sella which, without being pathological, was of uncommon type. The gynaecologist was familiar with the relationship of the ovaries to menstruation, and, with the physician, could be invaluable to the radiologist in planning a distribution of dosage over the endocrine system in such a way as to obtain the maximum therapeutic effect with the minimum amount of x-ray dosage to any one endocrine organ. The question whether a "stimulation" dose existed was important and had not been satisfactorily answered. Experimentally the evidence seemed to be against it. There could be no doubt, however, that temporary sterilization in a young patient could be obtained without difficulty by x rays, and did not in any way preclude a later possibility of normal conception and the birth of healthy children. Speaking generally, the use of x rays, as opposed to radium, appeared to

In a brief reply, Mr. Kilner outlined the objects of this newly formed society, which, he said, owed its successful conception, very properly, to Mr. Albert Davis. Manchester medical graduates who are interested in the society are asked to communicate with Mr. Davis (93, Harley Street, W.1).

Medical Society of Individual Psychology

The annual dinner of the Medical Society of Individual Psychology was held at the Florence Restaurant, London, on January 13. The chair was taken by Dr. H. C. Squires and the principal speakers were Dr. R. D. Gillespie of Guy's Hospital and Dr. Henry Harris. The latter took the place of Professor John MacMurray, who was absent through illness. Dr. Gillespie mentioned the relationship of the general practitioner to the psychiatrist and to psychotherapy, and stressed the importance of the Medical Society of Individual Psychology in that it existed for the purpose of helping general practitioners in the understanding of psychological problems. He went on to describe what appeared to the practitioner to be the diversity of testimony in the different schools of psychotherapy. But underneath this apparent disunity he believed there was the unity of truth. The various schools of thought had passed through states of aggressiveness, but he believed there were now to be observed signs of a *rapprochement*. He thought that the great need of the present time was for a council to make decisions upon the questions of nomenclature. Dr. Henry Harris spoke on the necessity of the general practitioner being sufficiently educated in psychotherapy to enable him to treat the early or minor forms of psychological illness just as he treated the minor forms of physical specialties—for example, ear diseases. If the general practitioner did not treat these minor psychological complaints, who could? It would not affect the consultant's livelihood; indeed, in the end he would benefit by the spread of knowledge. So would the patient and the general practitioner. The latter would come to treat his patient as a whole and not think separately of his body or of his mind. By means of the pamphlets it published from time to time the society had been instrumental in encouraging interest in the provinces and had many provincial doctors as members. Another thing it encouraged was tolerance, as members were not expected personally to profess the Adlerian doctrines. Tolerance should be expected from psychiatrists, who ought to have a wider view of life than others. Dr. Squires, in reply, emphasized the value of the society to the general practitioner. Not only were the meetings addressed by eminent psychiatrists of all schools of thought but the members were encouraged to bring their own difficulties in treating patients for discussion. The members of such a group could be of great help to each other. Dr. Cuthbert Dukes proposed the toast to "The Guests," and a message was sent to the president, Sir Walter Langdon-Brown, who was unable to be present, and to Professor MacMurray.

Health Campaign Meeting at Oxford

Speaking at Oxford on behalf of the Health Campaign, Mr. Kenneth Lindsay, Parliamentary Secretary to the Board of Education, said it was most satisfactory to know that Oxford was now linked in a most permanent and practical way with research and public health, largely owing to the Nuffield bequests. The Oxford and District Joint Hospital Board, with representation of local authorities and general practitioners and cottage hospitals, was one of the most progressive bodies in the country. As a city Oxford now had good facilities and equipment, and in many ways a good health record. He hoped, therefore, that out of Oxford, by bringing together clinical experience and laboratory knowledge, there might emerge a fresh outlook on the good life. But in contrast our universities, not excluding Oxford, were lamentably behind in physical education. A most interesting report entitled

Student Health had recently been issued by the National Union of Students.¹ After reviewing the meagre provision in our universities, the report suggests that all students should undergo systematic medical examination and that each university should have a director of physical education and also either a provident scheme, as at Oxford, or a compulsory levy for all students. It did not follow because a student had climbed successfully the educational ladder that he was a fit person at the top and could view the prospects with exhilaration. Mr. Lindsay concluded that as long as we spent £183 million a year on treatment of sickness and forfeited £100 million in lost time in industry we should need health campaigns to remind citizens of the ancient platitude that prevention was still better than cure. Mr. Ben Smith, M.P., after quoting the improvement in the vital statistics, pointed out that the country was spending to-day on sickness, its prevention, detection, and cure, upwards of £52,000,000 per annum; and that despite the great effort being made to improve the housing conditions there were still too many slums and far too much overcrowding. The best index to the success of the campaign for a healthier Britain would be to see the cost of detection, prevention, and cure of sickness falling rapidly as the health of the people improved.

INDIA

Child Welfare in Bombay

The number of live births registered in Bombay during 1936 exceeded by 5,971 the number of deaths in that city. This was equivalent to 5.1 per 1,000 population calculated on the census returns of 1931; there has been no such excess of births over deaths since 1866, the year in which birth-recording was instituted. The number of live births exceeded the figure for the previous year by 1,477 and the average of the last ten years by 9,856. The number of infant deaths registered was 8,946, compared with 8,455 in 1935; this represented a rise of 1,348 over the annual average for the decennium 1926-35. The commonest causes of deaths in infants remain diseases of the respiratory system, with infantile debility and premature birth, the last two conditions still being prominent in the first four weeks of life, while respiratory diseases exact their toll during the remaining eleven months of infancy. The campaign for the prevention of infantile mortality is going ahead, and in his report for 1935 as executive health officer of the Bombay Municipality Dr. J. S. Nerurker comments on the great value of the work done by the ten municipal nurses who visit the poorer homes and popularize elementary knowledge of the principles of hygiene and the prevention of disease, advising prospective mothers to take advantage of the maternity homes, and in some cases supplying bedding for their confinement at home and extra milk and bread during the first seven days of the puerperium. Sick persons are also guided by them to the municipal dispensaries. The proportion of births which were wholly unattended was 4.5 per cent. among the cases where inquiries were made, and that of confinements attended by unskilled women 17.9, these figures comparing respectively with 3.2 and 13.2 in 1935. On the other hand the proportion of childbirths attended by qualified midwives other than the municipal midwives rose to 3.3, compared with 2.8 in 1935, and the percentage of children born in hospital showed an increase of 9. The rate of maternal deaths is falling, it is noted that 70.9 per cent. of confinements took place in maternity homes, compared with 69.2 in 1935. The Infant Welfare Society has been actively engaged in home visits and milk distribution. Dr. Nerurker thinks that the daily milk consumption in Bombay (300,000 lb.) is still

¹ 3, Endsleigh Street, London, W.C.1.

In addition to the large quantity distributed by the public supply undertakings, even larger quantities were drawn direct from rivers, springs, and wells for agricultural and industrial requirements. Beet sugar factories, many textile works, paper works, and other factories, for example, each used several million gallons of water a day in manufacturing processes. Railway companies and most large works required large quantities for raising steam, and enormous volumes were used in condensers and coolers. The largest electricity generating stations each circulated 400 to 500 million gallons of water a day through condensers. Water for many industrial processes need not be of the same high chemical and bacteriological quality as drinking water. But water of high quality was necessary in the manufacture of foods and beverages, in the treatment of textiles, in raising steam, and in some other processes. The water distributed by many public supply undertakings, though suitable for domestic purposes, was in fact often unsuitable for certain manufacturing processes owing to its hardness or to the presence of substances detrimental to the quality of the products manufactured.

Problems of Pure Water Supply

Though it was generally recognized, Dr. Parker continued, that the purity of the water supplies was a major factor in public health, the average member of the community scarcely realized the problems of water supply and the precautions necessary in protecting gathering grounds and wells and in the treatment of water to ensure that the supplies distributed were absolutely safe for drinking and other domestic purposes. Public interest in the subject seemed to be aroused only at times of emergency, when there was a shortage of water during abnormally dry periods, or when there were outbreaks of water-borne disease such as occurred in 1932 at Malton and Denby Dale in Yorkshire, in 1936 near Sutton in Surrey, and recently in Croydon. Available sources of uncontaminated water, both surface and underground, were gradually being allocated. In some areas water had been withdrawn from underground sources for many years at a rate greater than that at which it had been replaced by natural percolation; there had in consequence been a marked lowering of the level of underground water in these areas. Many of the surface supplies were obtained from the upper reaches of rivers where there was little or no contamination by polluting discharges. Considerable quantities—several hundred million gallons a day—however, were drawn by public supply undertakings from the lower reaches of rivers below points of discharge of sewage and trade effluents of various kinds. These undertakings had to incur great expense and shoulder considerable responsibility in purifying the water before distribution.

With the provision of more houses with modern conveniences, and with developments in industry, there was certain to be an appreciable increase in the next few decades in the quantity of water of good quality required in this country. How this increase in demand was to be met would have to be seriously considered. It could be met provided that determined efforts were made to prevent undue pollution of the resources. Unfortunately many rivers and streams in Britain were badly polluted by sewage and trade effluents. In some areas discharges of waste liquids from factories had so polluted the water supplies most easily accessible to adjacent factories that they were quite unfit for the purposes for which they are required. Pollution not only caused difficulty in the provision of adequate supplies of water of the quality required for domestic, agricultural, and industrial purposes; it also adversely affected the fisheries, the recreations of the people, and general amenities. Dr. Parker then discussed some of the difficulties in preventing or reducing pollution by industrial effluents. With regard to the waste waters from the various branches of the milk industry, the work of the Water Pollution Research Board

had proved that the quantities of polluting matter carried away in the wastes could be greatly reduced by simple and inexpensive modifications in the operations within the factories to reduce losses of milk, whey, buttermilk, and other products and by-products. If adequate drainage trays were installed at all the depots and factories in this country the total saving of milk would be of the order of three million gallons per annum, or £150,000 per annum with milk at an average wholesale price for all purposes of one shilling a gallon. The investigation had also demonstrated on a large scale that the waste waters necessarily discharged could be efficiently purified by biological oxidation by methods similar in principle to those in operation at sewage disposal works.

Local News

ENGLAND AND WALES

Hospital Accommodation in the West Riding

Some time ago the West Riding County Council set up a composite committee to consider the question of hospital accommodation in the county administrative area. This committee visited hospitals in Yorkshire and other parts of England and on the Continent, and has consulted with representatives of the medical and administrative staffs of voluntary hospitals in the West Riding. In the committee's opinion 3,178 additional beds are needed for the county as a whole to provide accommodation on the scale of four general hospital beds per 1,000 of population. To meet the requirements of the several areas new hospital accommodation containing 1,250 beds in general hospitals should be provided, and the county council should co-operate with the governing bodies of hospitals for specialized forms of treatment. The Public Health and Housing Committee of the West Riding County Council, having considered the reports from the special composite committee, has adopted these recommendations, and recommends further that one hospital should be built in South Yorkshire between Doncaster and Barnsley, and another to the north of Leeds and Bradford to serve the north-west of the West Riding. A full account of these and other recommendations, and of proposals for further maternity accommodation, appeared in the *Yorkshire Post* of January 18.

London Manchester Medical Society

The first annual dinner of the London Manchester Medical Society was held at the May Fair Hotel on January 20 under the chairmanship of Mr. H. Pomfret Kilner and was attended by some fifty Manchester medical graduates at present in London. The principal guests were Sir Alfred Webb-Johnson and Professor E. D. Telford, and their health was proposed by Professor L. J. Witts, who brought them both within his own sphere by describing them as surgeons—men of blood and iron. To this toast Sir Alfred Webb-Johnson replied in a reminiscent vein. "The M.R.I." was proposed by Dr. Julius Burnford, who recalled the time when the Manchester Royal Infirmary was situated in Piccadilly and had as a resident surgical officer Professor A. H. Burgess. Professor Telford, in replying to the toast, said that the Infirmary continued to make progress and now had an active plastic surgery unit, which owed its initiation to the good offices of Mr. Kilner, a department of thoracic surgery, and a newly constituted unit for asthma research. An outward and visible sign of the advances which had been made was the "Plaster Palace," which was being reared up, so it was said, in order to accommodate Mr. Harry Platt's records. The toast of the chairman was proposed by Mr. E. B. Osborn, the only layman present.

and the profession. But the method is not cheap, nor in practice easy, while Sister Kenny herself has warned us that in the hands of any but her own pupils it may prove disastrous. If, therefore, at the end of the two to three years which she asks individual cases to wait patiently for the final cure, her claims should be found unjustified, what time, what money will have been wasted, and what heart-breaking disappointment awaits patients and relatives! It behoves the medical profession to make the most thorough and scientific investigation of this so-called new system. There is a notable contrast between the careful analysis made by Mr. Harry of thirty-eight cases treated from the early stages on orthodox lines by the highly qualified and experienced staff of the National Orthopaedic Hospital and the thirty-five cases referred to by Dr. Mills as having been treated by Sister Kenny from the onset (under her ideal conditions), but of which he gives no details. Dr. Mills concedes that 25 per cent. of all cases show spontaneous complete recovery; so that we are left with twenty-seven cases on which to judge the method. In Sister Kenny's own book only four or five such cases are described, while the thirty cases entrusted to her at Carshalton are still *sub judice*, as the committee appointed to report on them is not to do so till the autumn, the results having been inconclusive at the end of three months' treatment.

Mr. Harry's analysis shows dramatic improvement under orthodox treatment in all muscles which were not still entirely paralysed four to six months from the onset of the disease. Completely paralysed muscles, therefore, represent the problem in treatment. My only experience of Sister Kenny's methods is a visit with her to the cases under her treatment at Carshalton. These thirty cases did not present any favourable dramatic contrast to the same number of apparently similar cases treated during recent epidemics at the Bath and Wessex Orthopaedic Hospital, many of which have made the most astonishing recoveries: but, as I have already pointed out, this can occur apart from any specialized treatment, and hardly any two cases are scientifically comparable. An unfortunate feature in Sister Kenny's cases was that no detailed muscle charts were available to mark the degree of weakness before treatment was started and to measure progress. Even the muscle chart is subject to personal inaccuracies, but an unrecorded mental impression is even more unreliable. This is particularly so when the worker shows a certain vagueness of anatomical knowledge, which is noticeable in Sister Kenny's book (in spite of her debt to Dr. McKenzie) and in her handling of the cases. Despite her condemnation of splints, Sister Kenny uses a great deal of apparatus, the bulk of her book consisting of details about its construction. To an old-fashioned orthopaedic surgeon, trained by Robert Jones, Lovett, and Putti, her equipment seems antique and often ineffective—for example, her bands to control scoliosis are calculated to disturb the digestive organs even when they are applied correctly to the spine, and apparently her own staff are not always capable of so applying them. Furthermore, her horror of calipers and walking apparatus will induce her to keep bedridden for one or two years the type of case which the orthodox orthopaedic surgeon would have up and attending an ordinary school at the end of six months, which must surely be as sound on psychological lines as a further dose of Sister Kenny's blue curtains. Continuous supervision of such cases for thirteen years, with control of progress on the Harvard Research charts, has shown that they all develop into useful citizens, capable of earning a living wage even under the unfavourable trade conditions of the last decade.

It is sincerely to be hoped that the medical profession at the present moment will give to the extravagant claims made for Sister Kenny in the lay press the cautious Scottish verdict of "not proven," and will take every opportunity of testing them on unbiased and scientific lines. It would be most valuable if all the orthopaedic surgeons who visited Carshalton with her would record their findings.—I am, etc.,

M. FORRESTER-BROWN, M.S., M.D.,

Senior Surgeon, Bath and Wessex Orthopaedic Hospital.

Bath, Jan. 23.

Throat Carriers in Midwifery Practice

SIR.—In their paper recently published in this *Journal* (October 23, 1937, p. 811) Drs. J. L. Miller Wood and F. E. Camps, reflecting on certain cases lately before the courts, discuss the question of the risks in midwifery arising from throat carriers of haemolytic streptococci and set forth certain principles for our guidance. There will be general agreement with much of what they say of the carrier whose throat is manifestly unhealthy and of the procedure to be adopted when cases of infection arise. When, however, with one eye firmly fixed on the hazards of the High Court, they consider the problems of the "clinically normal" throat carrier, I think we are left rather more confused than before.

The nomenclature used is, I think, unfortunate. The authors do not here acknowledge how greatly the practice of serological "grouping" of haemolytic streptococci has simplified the problem of the healthy carrier. In one sentence they speak of "*Sr. pyogenes* Group A." To the general medical reader this may suggest that a Group A strain is one variety of *Sr. pyogenes*. In the rest of the paper they use the term *Sr. pyogenes* alone. Topley and Wilson (1936) have explained their reason for applying the name *Sr. pyogenes* to the haemolytic streptococci which belong to Group A. Either term is therefore correct, but "Group A" is the one now more commonly used and understood by those who are not bacteriologists. By its use the practitioner of midwifery and the public health officer are constantly reminded of the importance of differentiating these Group A strains which are responsible for most serious human streptococcal infections from those which belong to other groups and are relatively harmless. Moreover, it is not clear whether the authors are actually considering only Group A strains. Unless that is expressly stated their argument carries no weight, since only a proportion of the strains found in healthy carriers belong to Group A. They say:

"A certain public authority, before engaging its salaried midwives, recently swabbed their throats as a routine, and a high percentage of positive swabs was revealed, thus placing it in the curious dilemma of being unable to appoint midwives otherwise apparently healthy and with unblemished records without rendering itself liable to serious criticism in the event of subsequent infection occurring. It would appear more reasonable to examine the throats clinically in the first instance and only swab those with a suspicious appearance.

"It is inadvisable to swab all prospective contacts as a routine, since experience has taught that swabbing of clinically normal throats for no specific reason, as, for example, when a known case of infection has occurred, will almost inevitably lead to confusion. Further, the examination of swabs, unless performed by those experienced in working with the organism, is liable to yield a high apparent positive rate.

"The swabbing of clinically normal throats, unless they are believed to be a source of infection, cannot be too much deprecated.

"... there is reason to believe that if the throat is clinically normal the person is probably not infectious."

inadequate, in view especially of the prevalence of vegetarianism; larger schemes of milk importation have, therefore, to be devised, with particular reference to the needs and purses of the poorer people. There was a notable increase in the number of primary vaccinations, the percentage of known successes being 92.46.

The Pasteur Institute, Coonoor

During the year 1936 the number of patients treated at the Pasteur Institute, Coonoor, Southern India, was 493. No deaths from hydrophobia occurred among those treated; this is the fourth time in the thirty years' history of the Institute that the mortality rate has been *nil*. The Paris fixed virus was in use throughout the year for the preparation of Semple's carbolized sheep vaccine, and was in its 978th passage at the close of the year. No complications following treatment were reported. During the thirty years 1907 to 1936 the total number of patients treated was 36,604, and the number of deaths among them was 390, a mortality figure of 1.06 per cent. The work at the out-patient centres increased during the year under review, supplies of antirabic vaccine for 15,302 courses being issued, the mortality rate being 0.16 per cent. Out of the nine deaths among the incompletely treated, seven patients developed hydrophobia during the treatment; the other two ran away before the course had been completed. All these patients were Asiatics. The total number of deaths was nineteen, nine of whom were incompletely treated and ten completely treated. Two deaths followed jackal bites, one a fox bite; the remaining sixteen were due to dog bites. The shortest incubation period noted in 1936 was eleven days (after a jackal bite) and the longest 257 days (after a dog bite). The treatment given at the out-centres was the same as that at the Institute. Two cases of paralysis were reported during the year, both at out-centres. Thirty-four new treatment centres were opened in the Madras Presidency in 1936. The total number of doses of antirabic vaccine issued by the Institute was 210,147, as compared with 192,269 in the previous year. Major Jyengar, I.M.S., director of the Coonoor Institute, reports that special propaganda work was conducted in connexion with the Mysore Dasara Exhibition, which was attended by 150,000 visitors from all parts of the State of Mysore, and a lecture on the war against rabies was broadcast. The general clinical and bacteriological work of the Institute also increased in 1936, and postgraduate training was given.

Typhoid Fever in Calcutta

Week-end messages from Calcutta indicate that the recent small outbreak of typhoid fever in that city has now spent itself. It is more than three weeks since the last case was notified to the public health authorities. Most of the patients had been staying at one of the large hotels in Calcutta, and twenty-one Europeans from this hotel were still in hospital on January 23. By what means the infection was spread has not yet been discovered.

Lord Aberdare, chairman of the National Fitness Council, will open on March 2 an exhibition entitled "Health, Sport, and Fitness," which has been organized by the Royal Institute of British Architects at 66, Portland Place, W.1. The exhibition will remain open until March 31, and will then go on a tour of the principal cities and towns of England. It will consist of some 700 photographic enlargements, models, diagrams, and plans, divided into two main sections entitled "Everyday Health" and "Planning Physical Fitness." The first will show how health is secured and improvement can be made by town planning, collective health services, the provision of clean food, and by healthy living and working conditions in home, school, office, and factory. The second section will show how the extensive planning requirements of the Government's national fitness campaign can be best and most economically met.

Correspondence

Radio-active Pads

SIR.—It is being claimed that the use of these pads is authorized as an additional benefit by the Ministry of Health. I have inquired of the Ministry and am informed that "subject to the production by the member of an Approved Society of the necessary certificate by a medical practitioner with respect to the appliance required, it would be in order for the society to make a payment towards the cost of the hire of the apparatus for use by the member. . . . The claim that the treatment is curing 90 per cent. of cases of rheumatism among railwaymen is based solely on the letters which the society has received from members who have used the apparatus. . . . The power of the society to contribute to the cost of an appliance which has been recommended by a practitioner has been contained in the Additional Benefits Scheme from the beginning, and a statement to that effect by the Department is in no sense a special permission in regard to a particular appliance, and is certainly not an expression of approval as to the medical value of the appliance."

I would point out that the cost of 0.01 mg. of radium at the current price (£4,000 per gramme) is eight shillings; a pad sold for ten guineas with this amount enclosed in it therefore shows a great profit, particularly if the mineral ore be used in place of radium bromide. An electrically heated pad can be bought for about thirty shillings, and is an efficient means of treating rheumatic pain. If an electrically heated pad containing 0.1 mg. of radium be sold for twenty guineas the profit must be immense.

Hewitt, Pillman-Williams, and Russ found no benefit of the clinical conditions other than subjective on treating a series of cases of chronic arthritis with weak doses of radon. There is no trustworthy evidence of any biological action of such. A relatively large dose applied continuously for six days had no effect on the excised beating auricles of the frog's heart, suitably protected from infection and perfused with serum (C. M. Scott, *Sp. Rep. Ser. Med. Res. Council*, No. 223, 1937).—I am, etc.,

January 24.

LEONARD HILL.

Treatment of Anterior Poliomyelitis

SIR.—The articles in the *Journal* of January 22 on the treatment of acute poliomyelitis by Mr. Norman M. Harry (p. 164) and Dr. F. H. Mills (p. 168) will be read with great interest by all practitioners, because it is evident from the progressive incidence of poliomyelitis in Britain, even though the cases are of a mild type, that an increasing burden is going to be put on the profession for their treatment. It is therefore most desirable, in order to avoid waste of time and money, that the profession should face the problem with an agreed policy. The British Medical Association, by its reports on fractures and on physical training, has directed public activity and funds in these fields in an admirable manner. It is to be hoped that a similar unanimity will be attained in regard to the treatment of poliomyelitis. This is not easy to achieve, for the distribution of the paralysis and its rate of recovery are so erratic in this disease that almost any measure applied to a case is likely at one time or another to get the credit for a "miraculous cure."

The claims made by Sister Elizabeth Kenny and her pupils, such as Dr. Mills, for the attainment by her technique of nearly perfect end-results in about 90 per cent. or more of cases make her non-operative, "non-splint" methods very attractive, at first sight, both to the laity

A Spurious Record of Trichiniasis in Britain

SIR.—In a letter headed "Trichinosis" in your issue of December 18, 1937 (p. 1249), Dr. S. W. Sutton comments on the failure of Mr. van Someren to refer in his article¹ to "an outbreak among the boys on the training ship *Worcester*" reported about 1880 by Mr. Power of the Local Government Board.

I find that Mr. Power's report appeared in the Supplement containing the Report of the Medical Officer for 1879 in the Ninth Annual Report of the Local Government Board, 1879-80. It is entitled "On an outbreak of 'fever' that proved to be of the nature of trichiniasis on board the reformatory school ship *Cornwall*." The cases were clinically atypical and the "proof" is given in Appendix A: "Memorandum on microscopical examination, two months after death, of muscles and viscera from the body of Richard Pierce," signed by W. H. Power and Robert Cory. The memorandum (No. 6, pp. 47-64) is illustrated by three plates with eight figures. Even from a superficial examination of these illustrations one can say quite emphatically that the microscopical nematodes found were certainly not *Trichinella spiralis*. They have a double-bulbed muscular oesophagus of a type common in soil nematodes. This memorandum is immediately followed by a second memorandum (No. 7, pp. 68-77) by Dr. Charlton Bastian, F.R.S., who had been asked to examine and report on the drawings and specimens. Bastian carefully described and illustrated the worms anew, and identified them as males and females of a new species of free-living nematode which he named *Pelodera setigera*. His article is entitled "On some nematodes found in the body of a boy who had died from an epidemic disease (supposed to be trichiniasis) on board the reformatory school ship *Cornwall*."

From the above facts it is evident that Mr. van Someren would not have been justified in adding this "outbreak" to his list of reported cases of trichiniasis in Britain.—I am, etc.,

London School of Hygiene and Tropical
Medicine, Jan. 19.

R. T. LEIPER.

SIR.—In the *Journal* of December 11 (p. 1162) Mr. V. D. van Someren states that in the cases there recorded all those of trichiniasis which it had been possible to trace as having occurred in the British Isles were included. From this it appears that no other cases have been noticed in England, but I venture to think that others have been seen but not specially reported. I remember quite well at a post-mortem examination at St. Bartholomew's Hospital in 1913 or 1914 (I have no record of the exact date) seeing one case, and have a hazy recollection of a second at about the same time. The first case was that of an adult male who had died from some other cause. The abdominal muscles were simply one mass of trichinella larvae.—I am, etc.—

Coonoor, S. India, Jan. 6.

G. F. ROWCROFT,
Colonel.

Shortage of Calcium in the Diet

SIR.—Dr. Ian Murray suggested in your issue of January 22 (p. 202) that in our article on the shortage of calcium in the poorer-class diet (*British Medical Journal*, 1938, 1, 59) we had come to a false conclusion as to the inadequacy of the calcium content of this diet and that we had been led to this through a false analogy between the

needs of a relatively slow-growing organism like the child and a rapidly growing animal like the rat. The poorer-class diet which we used was described in full in our paper, and it certainly was deplorably low in dairy products, as the poorer-class diet always is. The fact that it did not contain sufficient calcium for growing rats was shown clearly in our experiments, and it was that which made us wonder whether it contained sufficient calcium for the growing child. A chemical analysis of this diet and of the tap-water of the Bloomsbury district showed us how much calcium a child would obtain provided he ate enough food to satisfy his caloric requirements and drank enough water to satisfy his thirst (average). Leitch's review in *Nutrition Abstracts and Reviews* (1937, 6, 553) told us how much calcium a young child requires, and the comparison of these two figures indicated to what extent the poorer-class diet was deficient in that factor. Undoubtedly if this diet is supplemented by three-quarters of a pint of milk per day (the school supplement is usually only one-third pint) much of the deficiency will be made good, but I would repeat that the calcium deficiency of the poorer-class diet that we described is an actual deficiency determined by comparison of the calcium content found by chemical methods and the generally accepted calcium requirement of the child. It is quite independent of any experiments on animals. Our conclusion, therefore, was drawn independently of the results of our rat experiments, which had in fact merely brought this deficiency to our notice in a most dramatic way.—I am, etc.,

London, W.C.1, Jan. 24.

KATHARINE H. COWARD.

Lower Abdominal Pains of Cervical Origin

SIR.—Dr. T. F. Tedd (*Journal*, January 22, p. 201) refers to possible untoward effects from alcohol employed for blockage of the pelvic nerves. During five years' experience, first with alcohol and later with procaine, I have seen no such results.

His second ground of criticism—the uncertainty of results based upon subjective pain sensations—is so commonly urged that I suppose it must often be relevant. Here, however, women who have suffered previous and sometimes multiple operations (appendicectomy, uterine fixation, removal of tubes and ovaries, hysterectomy, presacral neurectomy, etc.) without benefit respond as well as others. My long experience of ailing women has convinced me that, just as such pains in the lower abdomen felt year in and year out in the same region have a local physical cause, so the degree of relief is a real measure of the success of our physical procedures. I have seen nothing to make me suspect that in this large group, many seriously ill, the "personality of the individual doctor," or the other "camouflaging factors" to which Dr. Todd alludes, play an appreciable part. I would even protest that a sincere and intimate study of this well-defined pain entity must convince us that to seek an explanation for the relief in any influence other than that which is obvious is as idle as the common and often disastrous policy of lightly regarding similar pain entities as "psychogenic" because we fail to discover a local physical cause. As a corollary it follows that the subjective response is rarely ambiguous: an apparent anomaly has a true physical meaning. Thus, one-sided relief means imperfect blockage: the frequent persistence of the commonly accompanying backache after disappearance of the abdominal pain enables us to use the subjective response to differentiate out the elements in a combined pathology, while complete failure often points to an error in diagnosis.

¹ "The Occurrence of Subclinical Trichinosis in Britain. Results from 200 London Necropsies." *British Medical Journal*, December 11, 1937.

Thus the authors base their recommendations on "probabilities" and on personal experience of matters about which, so far as I can find, there is very little definite evidence. They argue that clinically normal throats do not carry strains capable of causing puerperal infection in a parturient woman if they gain entrance to the vagina. So confident are they that they emphatically deprecate any attempt to find such strains. Yet their faith is not so strong that they refuse to swab the clinically normal throat of a midwife who is a contact of a case of puerperal sepsis. They advise for such a "clinically normal" carrier whose streptococci are refractory to painting and gargling a seaside holiday and/or even tonsillectomy. In other words, they are content to wait for a case of sepsis to reveal a dangerous carrier and "deprecate" the attempt to find her by routine examination. It is here that I venture to join issue with Drs. Miller Wood and Camps.

In the first place, what is a clinically normal throat? Or, worse still, a clinically normal nose, for we know that the nose has its victims as well as the throat. I cannot think that even experts, much less general practitioners, public health officers, or bacteriologists, would be likely to agree on a standard of normality, nor do I think that such highly controversial evidence would be acceptable in a court of law. Therefore I strongly favour the use of the general term "healthy carrier" to describe a carrier with no history of recent or recurrent nasopharyngeal infection other than ordinary colds. Secondly, so far as I can find, there is no evidence to show how frequently and for how long such "healthy carriers" do carry Group A strains or whether such strains, though causing no symptoms in their host, may not become dangerous in conditions favourable to their pathogenicity such as exist in the genital tract after labour.

Before I ventured to enter the lists with Drs. Miller Wood and Camps I sought in vain from other laboratories for the evidence which is so urgently needed on these points. Hare (1935), examining 145 strains of haemolytic streptococci found in noses and throats, concluded that "on an average about 7 per cent. of normal persons have Group A strains in the upper respiratory tract." In my investigation into the source of infection in puerperal fever (1935) I had histories of nasopharyngeal infection in the carriers apparently responsible for infecting thirteen patients. Such histories were absent in the case of the other fifty patients, but since no direct inquiry was made for them this negative evidence is inconclusive.

Many local authorities now send to this laboratory or elsewhere swabs taken from their suspected cases or their carrier midwives. Strains isolated are "grouped" by a rapid technique. Very valuable information is thus obtained; an early diagnosis is made, potentially dangerous carriers of Group A strains are recognized, and the suspension of carriers of strains of other groups is avoided. It is, unfortunately, difficult to see how this service could be extended to include the collection of reliable information about antecedent infection in the midwives swabbed. In maternity practice as it is, however much we may deplore it, it is certain that persons suffering from colds or even slight sore throats will still attend confinements. If one of their patients should develop puerperal fever the attendant would be very likely when questioned to "have forgotten" or to make very light of the nasopharyngeal symptoms. Conclusions of scientific value could not be drawn from such data.

While awaiting evidence to the contrary, therefore, I shall continue to regard any carrier of a Group A strain as a potential source of danger; I sympathize with the expectant mother, who would rather know that her nurse

was swab-negative than that her nose and throat had gained the highest certificates of clinical normality; and I consider that it is part of our duty to our patients to discover and exclude carriers of Group A strains whenever it is practicable to do so. Unfortunately we know that it is not at present practicable to swab sufficiently often all persons engaged in midwifery. By even fortnightly swabbing we should spot the chronic carrier; but to ensure complete security it would be necessary to swab every midwife, say, two days before a confinement and to safeguard her from exposure to any infection after the swab had been taken—a procedure clearly impracticable except possibly in the highest-class domiciliary practice. In hospitals and nursing homes where maternity nurses are completely segregated from septic cases and their attendants sufficiently frequent routine swabbing might be practicable if there were an adequate reserve of nurses to replace the suspended carriers. Meanwhile, should we not cease to speak of "unsuspected sources" of infection? The modern antiseptic obstetric technique is so rigorous because we know that each patient is exposed to potential—that is, suspect—sources of infection from noses and throats—her own and those of her attendant and familial contacts, as well as from the dust of her room or ward.

Our experience in this laboratory fully supports the contention of Drs. Miller Wood and Camps that swabs should be taken only by competent persons and that they should be examined by bacteriologists experienced in this work. I would add that the person who takes the swab must satisfy himself that no antiseptic of any kind has been applied to the nose or throat for some hours previously; as a corollary to this, that no conclusions should be drawn from sterile swabs; and that the "all clear" report should depend on at least two consecutive negative swabs. From the medico-legal point of view it is always advisable to keep for at least six months stock cultures of puerperal infecting strains and of any nose or throat strains isolated at the time of the infection.

Some of the evidence given in the recent cases to which Drs. Miller Wood and Camps refer came as a shock to me. I wish that we as bacteriologists could do more than we do to convince practising doctors and nurses that it is deplorable to defer the diagnosis of uterine infection until the patient is very gravely ill or to reserve it for cases of "septicaemia" and so postpone until too late any search for the infecting organism and the source of the infection. From my revered teacher in gynaecology and midwifery, Professor Miles Phillips, I learned that "every woman is pregnant till you have proved she is not." In that generous spirit we should regard every case of fever in the puerperium as due to uterine infection till we have proved it is not. And there is only one way of proving it—by bacteriological investigation. We still have to persuade practitioners that for diagnosis the direct evidence derived from the examination of one vaginal swab outweighs all indirect evidence put together, not excluding that gained by a study of the character of "the swings on the temperature chart," as described by one witness. What you lose on the swings you gain on the swabs.—I am, etc.,

Treatment of Psychoneuroses

SIR,—I feel that some of the questions raised in the discussion have been dealt with satisfactorily, particularly by Dr. Ross in his last letter (*Journal*, January 15, p. 144). In my original communication one of the points I wished to emphasize was the tendency to overcrowding in the psychological department—a tendency which, in view of the long time necessary for dealing with any single case, is not felt to the same extent in other medical out-patient departments. As Dr. Ross states, "if the doctor is to have half a dozen new patients sent to him every time he comes to the clinic the thing cannot be done." Dr. Ross, like myself, has realized this particular difficulty, and to meet it he offers a valuable piece of constructive criticism—namely, the necessity for impressing on other members of a hospital staff the utility of the department. This is undoubtedly the solution of the problem, and it will be accomplished in time; but again, as he says, "there are many important physicians and surgeons who do not yet believe that our labours are of much value for the present or of promise for the future." It was the recognition of this very fact that called out my original letter.

Until the medical student is given some elementary knowledge of modern psychotherapy this attitude of scepticism will remain, and it is to be hoped that with increasing facilities for such instruction being included in the curriculum the next generation of general practitioners will have sufficient interest in the neuroses to attempt to deal with them in the consulting room. Like Dr. Ross, I am not now referring to those cases for which special knowledge of psychotherapy is demanded—for example, cases of profound obsession—but to the general run of so-called functional cases—neurasthenia, traumatic neurosis, and the like—which could, I think, be dealt with satisfactorily by the general practitioner if he had sufficient interest, which can only be attained by adequate instruction.

Finally, if I might venture to mention one other difficulty which is very obvious in my own practice, it is that the educational attainment, or rather the standard of intelligence, of the patient is a very important matter. It is probably a little lower here than in London and the south generally; it is well-nigh impossible in many cases to attempt any form of explanatory therapy, and one is driven to the use of suggestion in one way or another. But any form of therapy which offers a hope of improving the economic position of a patient out of work is an advantage, and even in quite illiterate labourers, perhaps sometimes because of their illiteracy, suggestion therapy may be successful. Nevertheless one feels that, though removal of a symptom by suggestion may be satisfactory, it is merely an anodyne, and that some form of mental exploration is the method of choice whenever possible. Such mental exploration need not, as Dr. Ross points out, be very deep; in fact it may often be kept on the conscious level and yet be truly curative. The really deep mental analyses can be looked upon as rather in the nature of research problems and not essential to clinical therapy.—I am, etc.,

Sheffield, Jan. 19.

E. FRETSON SKINNER.

Medical Hydrology

SIR,—A report which appeared in the *Supplement* of January 15 (p. 35) of a lecture on spa treatment and rheumatism that I gave to the Plymouth Division of the British Medical Association has just been brought to my notice. In it I am reported to have said that I "did not consider that the mineral content of the waters was of any special importance." What I actually said was that I had not "time to deal with the merits and demerits of various types of mineral water"; and again that "this was a difficult question when one must tread warily," meaning that benefit from the treatment of rheumatism must depend largely on clinical impressions, and no one has the necessary clinical experience of all "waters." I am sorry if these remarks were misunderstood.

May I endorse the remarks made by Dr. Alfred Cox in the *Journal* of December 18 (p. 1249) with regard to the necessity for teaching the student more about the treatment of rheumatism and of the value of hydrotherapy and spa treatment. Scientific hydrotherapy, best combined with rest and change of surroundings at a spa, is invaluable, but it is only one part of the treatment. If the best results are to be obtained each individual must be considered from every aspect and a programme drawn up to include physiotherapy, orthopaedics, removal of sepsis, vaccines, gold, etc., according to the individual's requirements. Until the student is taught this there will be no true balance; either he will be a spa addict believing in the supernatural power of the waters to cure all ills or he will consider spa treatment quackery. There is in existence a Committee for the Study of Medical Hydrology in Great Britain, which has formed a panel of lecturers consisting of men specializing in this science from all over the country. They are willing to give lectures to any medical students' or practitioners' society. I shall be glad to furnish further particulars to anyone interested.

We are attempting to rationalize treatment, but it is only by obtaining recognition in the medical curriculum that we can satisfactorily do so. At Leeds University this recognition is forthcoming; lectures are given and questions asked in examinations under the heading of therapeutics. Several lectures have also been given to students' societies at the London hospitals. It is time the young practitioner knew more instead of less than the average layman about hydrotherapy. It is, to say the least of it, ignominious to show a complete lack of knowledge when asked questions by one's patient.—I am, etc.,

G. D. KERSLEY.

Bath, Jan. 24.

The Problem of the Final M.B., B.S. Lond.

SIR,—As the present discussion on this subject, which is vitally important to London medicine and its students, seems to have degenerated into a personal and political one, and as this seems likely to obscure the real point at issue, may I state the case from the point of view of one who has no axe to grind?

The primary cause of the falling away from the final examination of students who have started upon its course is the fact that the Conjoint Board offers to the student an easier examination (at a considerably heavier charge) which he can begin taking six months before the completion of his medical training, which he can take in parts, and which allows him to take any part he has failed in again in three months' time. Herein lies the key to that £16,000 which the financial foresight of the Colleges

To answer Dr. Todd's other point: in the present state of our knowledge a problematic and minor risk does not justify the refusal of nerve blockage for that large residue in whom cervical drainage alone fails to give complete relief. In 183 cases there were forty-eight such—that is, about 26 per cent.—many sorely tortured women.—I am, etc.,

British Postgraduate Medical School,
London, W.12, Jan. 24.

JAMES YOUNG.

Rehabilitation Centres for Injured Workmen

SIR,—Mr. W. J. Eastwood, in his letter on this subject (*Journal*, January 22, p. 202), quotes from two sources figures in connexion with permanent incapacity from industrial injuries. On the one hand he refers to the evidence given before the committee to the effect that the inevitable permanent incapacity rate is less than 5 per cent. in organized clinics, and on the other hand he quotes a large insurance company as stating that the figure for "some permanent incapacity" is about 35 per cent., irrespective of whether the clinic is organized or not. In asking for an explanation of the discrepancy, and in making a plea for the avoidance of overstatement, Mr. Eastwood will have the sympathy of all. There is a growing interest on the part of the Government in the organization of centres for the treatment of industrial injuries, and the British Medical Association is to be congratulated on fostering it. It is important that its growth should not be retarded by doubts as to the accuracy of statistics which so strongly suggest the necessity for an extension of organization and the immediate establishment of an experimental rehabilitation centre.

From a personal knowledge of the work of organized clinics in the Liverpool district I am satisfied that there will be fairly wide variations in both directions from the 5 per cent. rate for permanent incapacity. To instance the possibilities, may I refer to fracture of the shaft of the femur? This injury is liable to produce a deficiency of flexion of the knee of about 10°. So far as a dock labourer is concerned this disability, though possibly permanent, does not prevent him from returning to his work, and he is not regarded from an insurance company's point of view as "permanently incapacitated." If, however, the patient is a collier, then he is unquestionably incapacitated, since his work demands nothing short of full flexion of the knee. Similarly, an orthopaedic surgeon who is unfortunate enough to sustain a fracture of the terminal phalanx of the big toe need not cease work even for a day, while the average duration of incapacity for a dock labourer who suffers from this common injury is nearly five weeks. In these and many other possible comparisons, does there not lie an answer to the doubt which has been raised as to the accuracy of the figures given in evidence to the committee? Is it not possible that the figure was arrived at from a consideration of injuries treated in clinics where there is a small proportion of workers in the heavy industries? Of all vocations that of a collier demands the strictest and most rigid criteria in regard to fitness for work.

It may be suggested that this factor alone cannot explain the discrepancy. I find the insurance company's figure quite incredible, and am confident that your correspondent could produce statistics from his own clinics which would demonstrate that the 35 per cent. incapacity rate is an "overstatement," in deploring which all will join him. A true estimate of the value of organization in the treatment of injuries can be arrived at, not by comparing one hospital with another but by comparing

statistics for, say, Merseyside, where organization is fairly well advanced, with those of some other similar district in which it is manifestly absent. It is possible that insurance companies are in possession of such statistics, and it is to be hoped that they will be presented as evidence before the committee. There can be no possible motive for overstatement by the surgeons from whose clinics the figures were obtained. Those whose work lies in the treatment of injuries must surely be unanimous in affirming that the case for organization and for the establishment of rehabilitation centres is so strong that every possible investigation by the insurance companies, or by the Government, is to be welcomed. The financial support of the insurance companies is needed as urgently in the personal interests of the workers as in their own pecuniary interest. The establishment of organized clinics and rehabilitation centres will prove as sound a business proposition in this country as it is reputed to have been for years in Vienna.—I am, etc.,

M.Ch.(Orth.), F.R.C.S.

Acriflavine Emulsion

SIR,—In the article on the use and abuse of antiseptics in the *Journal* of December 25, 1937 (p. 1286), Professor Garrod and Mr. Keynes point out that the antiseptic action of acriflavine in the treatment of infected wounds is "hindered by intimate admixture with an oily basis, as in the acriflavine emulsion of the B.P.C." They also state that "this elaborate preparation has no demonstrable antiseptic action whatever." In the *Prescriber* of June, 1935 (p. 207), I published a formula for making readily, simply, and cheaply an elegant and highly antiseptic emulsion of acriflavine, as follows:

Acriflavine, B.P.	1 gm.
Lime water, B.P.	500 ml.
Olive oil, B.P.	500 ml.

Dissolve the acriflavine in the lime water, add the oil, and shake thoroughly. (A slightly rancid commercial olive oil is more satisfactory than a highly refined salad oil on account of its higher fatty acid content.)

Acriflavine is acid in reaction, but its solution in lime water in no way diminishes its efficacy as an antiseptic whatever chemical change may occur through its solution in an alkaline liquid. As is well known, its bactericidal action is increased in the presence of serum, also an alkaline fluid. While acriflavine is freely soluble in water (1 in 3) and in alcohol, it is highly insoluble in fixed oils and other organic solvents. On account of this insolubility in oils various methods have been devised to make an emulsion of it, and those so far advanced have been more or less complicated and time-consuming.

The acriflavine emulsion of the B.P.C. is prepared as follows:

Acriflavine	1 gm.
White beeswax	41 gm.
Distilled water	250 ml.
Liquid paraffin	750 ml.

Melt the white beeswax in the liquid paraffin and add with constant stirring a warm solution of the acriflavine in the distilled water; stir until cold.

The emulsion made with lime water and olive oil is, *per contra*, simply and quickly prepared; it ensures complete solution of the acriflavine, and provides an elegant and highly antiseptic preparation which is particularly soothing and healing in cases of burns of lesser degree and of scalds. Though stable, the component parts of the emulsion may separate slightly after some time; the con-

SIR.—In the letters on this subject which appear in the *Journal* of January 15 both your correspondents strike the same note. Both complain that there are available in London at the same time two qualifying examinations, and that therefore there is entailed needless work for two sets of examiners and double expense for the students or their parents. Why fix on the number two? There used to be more in my day—nearer the round half-dozen if one counted those in the provinces as well. Such arguments as those contained in your correspondents' letters are entirely beside the point, which is of far greater importance than one would judge from their letters. Sir Ernest Graham-Little in the latter half of the opening paragraph of his letter in the *Journal* of January 22 puts the matter clearly; and I would especially draw to this letter the attention of all London graduates and others interested in this question.—I am, etc.,

Llandilo, Carm., Jan. 24.

J. H. LLOYD.

Correct Footwear

SIR,—In the correspondence on this subject I have looked in vain for any suggestions as to what constitutes correct footwear. If one examines the average shoe after it has been worn for some time the sole is usually most worn along its outer border, showing that the principal weight of the body is carried by the outer side of the foot. When the normal foot is on the ground most weight is borne by the heel, the inner arch, and the great toe. The foot is slightly everted and abducted, and there is no lateral movement at the ankle-joint. If the weight is displaced outwards, as in the modern shoe, the foot becomes inverted and adducted, and the weight falls on the outer arch and the distal portion of the transverse arch formed by the heads of the metatarsals. The latter collapse and draw down the corresponding phalanges with them. This causes apparent shortening of the toes by tilting them upwards and backwards. This movement is resisted by the upper of the shoe, and deformity results. The toes become crowded together and pressed against the shoe, corns, callosities, hammer-toes, etc., resulting. The toes may become twisted or displaced either behind or in front of their neighbours, and show evidence of pressure from the shoe, from the other toes, or from both. The great toe no longer supports the body weight, tends to be displaced outwards, and may lie against the second toe or above or below it; a bunion sooner or later develops on its metatarso-phalangeal joint.

The aim of treatment is to bring the foot back to the position of slight abduction and eversion, with the body weight supported by the heel and great toe. This is done by building up the sole of the shoe to make a curved inclined plane centred on the metatarso-phalangeal joint of the great toe, and by stiffening the remainder of the sole to the heel. This raises the depressed metatarsals and outer side of the sole, keeps the foot everted, and displaces the weight of the body to the heel and great toe. The fore part of the foot is broadened and the toes are no longer crowded together. The phalanges are straightened and the foot is lengthened; the balance of the body is restored.—I am, etc.,

London, N.11, Jan. 23.

W. SIMPSON.

Pasteurization of Milk

SIR,—May I thank Dr. Maule Horne for his courteous letter and regret that Dr. Hawthorne's was not equally so (*Journal*, January 22, p. 199). The milk supply of our great towns is in a parlous state, and possibly nothing but

pasteurization can make it endurable, but that is no reason why more wholesome methods should not be tried wherever possible. My letter (January 15, p. 148) was written simply to give an account of our experience, and to plead that compulsory pasteurization for the whole country would be a great mistake. Dr. Hawthorne's assumptions are great, but one should be contradicted at once in the general interest. Letchworth is not a "rural retreat" which has no relation to the busy life of the people. The foundation of Letchworth has been the most successful piece of public health work in this country during the past thirty years. It is characteristic that it is far better known and imitated abroad than in England, and Dr. Hawthorne will be interested to hear that our "rural retreat" contains over a hundred factories.—I am, etc.,

Letchworth, Jan. 22.

NORMAN MACFADYEN.

INTERNATIONAL CONGRESS FOR PSYCHOTHERAPY, OXFORD, 1938

From July 29 to August 2, in Balliol College, Oxford, the International Medical Society for Psychotherapy will hold its tenth annual congress. The first event will be a reception on the Friday night. Papers will be read and discussed on Saturday morning and afternoon, Sunday afternoon, Monday morning and afternoon, with intervals for entertainment and recreation, and the Congress will break up at midday on Tuesday.

The Congress is under the presidency of Professor C. G. Jung, who is assisted by a Council representative of the British Medical Association, the Medical Section of the British Psychological Society, the National Council for Mental Hygiene, the Child Guidance Council, and several other bodies, and in co-operation with the Board of Control. The languages of the Congress will be English, German, and French. Summaries of the papers read will be provided for all members in the three languages; adequate interpretation will be provided for the discussions. Delegations have been invited from Germany, Austria, France, Holland, Switzerland, U.S.A., Rumania, Hungary, Czechoslovakia, Poland, Norway, Sweden, Denmark, Belgium, Italy, and it is hoped that a large and representative number of British delegates will attend to welcome and exchange views with their colleagues from abroad.

The purpose of the International Medical Society for Psychotherapy is to provide a platform for all schools of medical-psychological thought; and the characteristic of the congresses held by it hitherto has been the catholicity of approach. Up to 1936 the society held its congresses in Germany. The 1937 Congress met in Copenhagen; and this year's meeting in Oxford will be the first occasion on which a congress of the society has taken place in an English-speaking country. At the last Congress it was decided that one of the main themes for discussion in 1938 should be psychotherapy at the various periods of life.

Details concerning the programme and accommodation will be announced later. The fee for membership of the Congress has been fixed at a sum not exceeding 17s. It would greatly assist the organizers if all those interested in or intending to attend the Congress would communicate immediately with the honorary secretary, Dr. E. B. Strauss, 81, Harley Street, London, W.1.

As there are so many specialized sections of applied chemistry which are on the fringe of the work of the Society of Chemical Industry's subject groups, such groups are to be allowed to form panels. The first panel will deal with microbiology as applied to all industries utilizing micro-organisms—for example, food, agriculture, dairy, leather, and the fermentation industries. At the same time the panel will deal with the prevention of micro-organisms and such subjects as the microbiological spoilage of raw or manufactured materials.

manages to guide into their otherwise rather empty coffers.

The arguments of the students with whom I have discussed the matter are these: (1) That they can begin taking the Colleges' examination six months before they can sit for that of the London University. (2) That by taking it they can with more certainty qualify up to time and are then "off" their parents' hands—a noble aspiration. (3) That if they fail in the M.B., B.S. they are referred for six months against the Colleges' three. (4) That when qualified they can take a hospital appointment, or otherwise earn a living, and can take the London University examination at leisure—a dangerous argument, as experience proves. (5) That it gives them practice at writing examination papers, at which they get no practice in their particular hospital. Lastly, there is one argument which is not always mentioned, and that is that some of them are in a hurry to get married.

In my opinion these arguments are theoretically sound, and if the intentions which they embody were carried out there would be little to say against them, save that they carry with them that awful waste of £16,000, which might be used to greater advantage to the students. But results show that the ambition to take the higher examination too often fades away, and the reasons are not far to seek. If I put aside the powerful narcotic effect of the drug prescribed by Cupid the following appear to me to be the more important. (1) The student is called upon to take the London examination almost immediately after the completion of that of the Colleges; he finds himself examination-weary, and is unable to summon the necessary grit for further work. (2) By taking the Colleges' examination in parts he almost certainly neglects those subjects in which he has passed to concentrate upon those for the final part, and these neglected subjects will have to be revised in the short time between the two examinations. If he fails in the M.B., B.S. examination he has to wait another six months before the next examination. On the assumption that he passes at the next attempt he will have spent a whole year in taking mere qualifying examinations—an unjustifiable waste of time in the life of a medical man. Is it to be wondered at that only the more determined students are willing to face these conditions?

There is no doubt that all these troubles could be avoided by the institution of a State examination, and this should be our ideal to aim at. But while the State examination lingers there is much in the present trouble which could be avoided if the London examinations were held four times a year instead of twice. The examinations would be no easier, and much time and money would be saved. It would also enable the examiners to refer candidates for three, six, or more months according to the knowledge they have shown, and thus failure would not fall so heavily upon those who have only just failed to satisfy the examiners.

I have no wish to enter into the discussion of any other point in relation to the London examinations, of which I know there are many. I wish only to emphasize the opinion that if the examinations were held four times a year instead of twice the number of students entering for the examination would certainly be greater. And I feel sure that if the University could manage to make the change in the near future they would receive the gratitude of all their medical undergraduates.—I am, etc.,

STANLEY COLYER, M.D., B.S.Lond.

Mayfield, Sussex, Jan. 24.

SIR.—Had the subject under discussion been the number of University students taking the M.B., B.S. degree, then

there would be some point in Sir Ernest Graham-Little's argument; but we have not been discussing this, but the percentage of students taking the degree. This being the case his deductions are not at all obvious.

I should not have thought that any statement of mine could be interpreted as suggesting that the Court had acquiesced to any lowering of the standard of the degree examination. Everyone who has anything to do with the University of London knows that the Court does not concern itself with academic matters, and therefore would not be in a position to know anything about the standard of the examination. Any remarks of mine, therefore, on this subject can clearly not have been applied to the Court.

Sir Ernest again repeats a statement which he made in the Graduates' Association manifesto that the Faculty Board proposed that "the examination in medicine, surgery, and midwifery for the final M.B. should in effect be conducted by the Conjoint Board on its present standard." Had Sir Ernest taken the trouble to read the Senate minutes on the subject he would have found that "the Faculty Board have come to no decision in regard to these suggestions."

Professor Greenwood's peculiar form of humour makes it rather difficult to follow his arguments. In any case the tone of his letter relieves me of any necessity for a reply.

A great deal has been written in the course of this correspondence that must be very confusing to those who are not thoroughly conversant with the internal workings of the University. As I do not propose to trouble you with any further letters on the subject, may I just again point out what are the real points at issue. In order to find a solution to the problem of the small percentage of University medical students who take the M.B., B.S. degree, the Senate has authorized representatives of the Board of the Faculty of Medicine to consult with the Royal Colleges. No proposals have been made by the Board and the field of discussion is entirely open. Any proposals that emanate from the conference will have to be referred to the Senate, and Sir Ernest Graham-Little and his friends will have ample opportunity to debate them. It seems to me a little unfortunate that Sir Ernest should have used a senatorial election in an attempt to hamstring these discussions from the start, and particularly that he should imagine that the support Mr. Mitchiner has received was entirely due to objections to the action of the Senate without taking into consideration the personal popularity of the candidate or the methods employed in obtaining that support.

As I pointed out in my first letter, Sir Ernest and his friends appear to take no interest in the student or in his educational career. They must be aware of the difficulties in arranging suitable courses of instruction for students who are preparing for the two sets of examinations which overlap in point of time, and they must further be aware of the strain, both mental and financial, which the present system entails. Fortunately, the Senate as reconstituted under the Act of 1927 (which Sir Ernest so vigorously opposed both in and out of Parliament) includes for the first time among its members some of the deans of the medical schools. Thus people with a practical knowledge of these problems now have some say in the policy of the University. They realize that the Conjoint Board cannot be dismissed as a negligible factor, and that the present condition can only be improved by cut-throat competition or by co-operation. Of these two choices the latter appears to be the more desirable. Only by conference is it possible to say whether it is practicable.—I am, etc.,

London, W.1, Jan. 24.

A. M. H. GRAY.

tion, and the Dean Orphanage, all educational institutions, and he was for many years a member of the Education Authority of Edinburgh. He had for long been one of the directors of the Royal Blind Asylum, and recently became chairman of the managers of the Thomas Burns Home for Blind Women. He was prominent in the activities of the Church of Scotland, having been for many years one of the leading members of St. Cuthbert's Kirk Session, Edinburgh, and from time to time a member of the General Assembly of the Church of Scotland. He was physically a man of great activity and a keen golfer, curler, and bowler.

Dr. Sym is survived by his widow and by several sons and daughters, of whom one daughter is an M.D. of Edinburgh University and a son is at present a student of medicine. A funeral service was held in St. Cuthbert's Church, Edinburgh, on January 22, which was attended by a large number of professional colleagues and of representatives from the various institutions with which Dr. Sym had been connected.

OTTO LEYTON, M.D., D.Sc., F.R.C.P.

Physician to the London Hospital

We announce with regret the sudden death on January 21 of Dr. Otto Leyton, physician to the London Hospital, who was well known for his clinical studies on diabetes. A letter from him on one aspect of insulin therapy appeared only last week in our correspondence columns.

Otto Fritz Frankau Grünbaum (he changed his name by deed poll to Leyton in 1915) was born on October 20, 1873, the younger son of Joseph Grünbaum, a naturalized British subject. His elder brother Albert, who died in 1921, had been professor of pathology in the University of Leeds. From the City of London School he went to Trinity College, Cambridge, and there gained first-class honours in Part I and Part II of the Natural Sciences Tripos. He continued his medical studies at St. George's Hospital, took the M.A. Cantab. in 1898, the B.Ch. in 1900, and proceeded M.D. in 1904, having in the meanwhile obtained the M.R.C.P. diploma and the D.Sc. degree of the University of London. He had been house-physician at the West London Hospital, and was for a time assistant physician at the Belgrave Hospital for Children and physician to out-patients at the City of London Hospital for Diseases of the Chest. For some years before election to the visiting medical staff of the London Hospital he worked as clinical pathologist at King's College Hospital. In 1909 he became a Fellow of the Royal College of Physicians. At the London Hospital Medical College he was lecturer on therapeutics, and he had examined in pharmacology for the University of London. He was honorary secretary of the Section of Pathology at the Annual Meeting of the British Medical Association in Belfast in 1909, and vice-president of the Section of Pharmacology and Therapeutics and Dietetics at the Aberdeen Meeting just before the outbreak of war in August, 1914. Two years later he published a paper on the examination of the soldier's heart, and a book embodying three lectures on the treatment of diabetes mellitus by alimentary rest, expounding the method known as the "Allen" treatment, of which a full abstract had appeared in the *British Medical Journal*; he also contributed chapters on the internal secreting glands to the fourth and fifth editions of Price's *Textbook of Medicine*.

Dr. Leyton leaves a widow, and one son and one daughter. The funeral took place at Medmenham, near Marlow, on January 25, and a memorial service was held in the chapel of the London Hospital at the same time.

Many members of the medical profession, particularly those interested in tropical hygiene, will have heard with regret of the death of Major ERNEST EDWARD AUSTEN, D.S.O., late Keeper of Entomology at the British Museum (Natural History). Austen joined the staff of the Museum in 1889 as an assistant in the Department of Zoology, from which the Department of Entomology was separated in 1913. He took part in the first expedition of the Liverpool School of Tropical Medicine to Sierra Leone and served on many committees investigating trypanosomiasis and the tsetse fly. He was a member of the committee of management of the Imperial Institute of Entomology and wrote valuable books and pamphlets on blood-sucking flies. Major Austen served at first during the war as a combatant officer, but was transferred later to the Egyptian Expeditionary Force for special duty on malaria and other insect-borne diseases.

Dr. ROBERT ENWRIGHT LAUDER, formerly medical officer of health for Southampton, died at his home in Millbrook Road on January 19, at the age of 73. He took the qualifying diplomas of the Edinburgh Royal Colleges in 1886, the D.P.H. in 1890, the F.R.C.S. Ed. in 1893, and the M.D. of Durham University in 1906. After serving as a medical officer for the South African Field Force in the early part of the South African War Dr. Lauder was appointed in 1901 medical officer of health under the county borough of Southampton and the Port Sanitary Authority; he was also medical superintendent of the borough and port fever hospitals, medical officer to the Education Authority, and medical inspector under the Aliens Act. During the great war he was medical officer in charge of the University War Hospital at Southampton, and officer commanding the 7th Sanitary Company, R.A.M.C.(T.). Dr. Lauder joined the British Medical Association in 1903, was chairman of the Southampton Division in 1922, and again from 1928 to 1930, in which year he resigned his appointments in the Public Health Service. He was responsible for twenty-nine consecutive annual reports on the health of the borough and port of Southampton.

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on January 20 the following medical degrees were conferred:

D.M.—A. M. G. Campbell.
B.M.—T. Gadian, C. W. Rayne-Davis, I. B. Pirie, C. M. F. Walters

UNIVERSITY OF CAMBRIDGE

At a congregation held on January 22 the following medical degrees were conferred:

M.B., B.Ch.—S. R. F. Whitaker, *J. B. Bunting, *D. O. Wharton, *B. D. Whitworth, J. K. Denham, E. H. L. Wigram, J. Sutcliffe, A. S. Bookless, K. S. Mullan, D. A. P. Anderson, J. L. Griffith, C. F. UNIVERSITY OF LONDON

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The following candidates have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN PUBLIC HEALTH—Part I: S. Amarasinghe, P. H. R. Anderson, S. N. Chelliah, F. C. L. B. B. Crawford, P. A. Crowley, L. D. P. Dharmaratne, C. W. Dixon, R. Y. Dunlop, A. C. Gee, F. W. Gilbert, M. G. Hyder, O. G. Lloyd, A. L. St. A. McCloskey, G. A. Macgregor, I. M. Macgregor, M. Markowe, J. S. Minnett, F. Norenha, P. X. O'Dwyer, S. S. Pillai, A. I. Ross, A. F. H. Stewart, Emily S. O. Thomson, S. C. Thurai-Rajah, M. Watkins, Helen E. Wight.

Medico-Legal

A GAP IN THE POISONS ACT

By the Pharmacy and Poisons Act, 1933, the poisons in Part I of the Poisons List can only be sold by an authorized seller of poisons—that is, a member of the Pharmaceutical Society. The society constantly prosecutes unauthorized retailers for selling drugs containing Part I poisons, which are numerous. Recently the society prosecuted a "drug-store keeper" for selling asthma tablets containing ephedrine, which is a Part I poison.¹ The solicitor appearing for the society said that the packet was not marked "poison," but bore a warning that it was dangerous to exceed the stated dose. The retailer said that he stocked many thousand varieties of drugs, and that this medicine had been ordered by an assistant without his knowledge. The solicitor pointed out that the Pharmacy and Poisons Act, 1933, imposed no restrictions on wholesalers, and that anyone could order any quantity of poison he wished from a wholesaler. The magistrates imposed a small fine.

The class of persons exempted from the working of the Act is very large, and to throw on the wholesaler the responsibility of selling poisons only to certain persons would be to impose a severe and perhaps unfair burden. On the other hand, the Act is doubtless evaded or ignored by a number of retailers, and the Pharmaceutical Society's inspectors may be unable to prosecute in more than a small proportion of cases of infraction of the Act. It ought to be possible to devise some measure of control which, while not unduly hard on the wholesalers, would prevent Part I poisons coming into the hands of persons who are not authorized to sell them.

PROBATION AT MENTAL HOSPITAL

A Legal Experiment

Sexual offenders are apparently becoming more numerous, and give great trouble to magistrates' courts. The offenders are usually not criminals at all, but victims of some psychological disorder which may be amenable to treatment. Facilities for treatment are slowly becoming available in large centres, and magistrates are recognizing its value. One of the best-known agencies in London is the Institute for the Scientific Treatment of Delinquency. In the provinces, however, where out-patient clinics for psychological disorders are few, patients of this kind are sometimes best treated as in-patients at a mental hospital, where the staff are willing and able to look after them. The Wakefield magistrates recently² made a probation order in the case of a young man charged with a sexual offence, containing a condition that he should enter a certain mental hospital for six months as a voluntary patient. The court was satisfied that the offence was the result of a mental abnormality, and the man was eager to be helped to overcome it and willingly consented to the condition. The magistrates, in imposing this condition, expressly took the risk that they were acting beyond their legal powers, and hoped that, if they were, the law would soon be amended to enable magistrates to impose residence at a mental hospital as a condition of probation.

The Probation of Offenders Act, 1907, Section 1, which introduced probation for the first time, as amended by the Criminal Justice Administration Act, 1914, s. 8 (2), provides that when a court thinks that the charge is proved but that it is expedient to release the offender on probation it may, without proceeding to conviction, make an order discharging the offender conditionally on his entering into a recognisance to be of good behaviour and to appear for conviction and sentence when called on at any time

during the period of the order. The order may contain several conditions, including supervision by a named person and of a particular kind, and such additional conditions with respect to residence and any other matters as the court may, having regard to the circumstances, consider necessary to prevent the repetition of the offence. Obviously, a court could not impose a condition that the offender should become a voluntary patient at a mental hospital if he did not wish to do so or the hospital superintendent did not wish to accept him. Indeed, no good purpose would be served by making this condition. If, however, the offender consents to be a voluntary patient and the hospital will take him, the language of the Act appears amply wide enough to allow the court to make his residence at the hospital as a voluntary patient a condition of the probation order. As a matter of everyday fact, every condition for a probation order is really imposed with the consent of the offender, and the value of the method depends on his co-operation. The legal validity of this probation order can only be called in question on appeal to quarter sessions. In the circumstances no one is likely to lodge an appeal, and as no court is likely to be imprudent enough to impose such a condition against the desire of the offender, the Wakefield example may be followed for some time before its legal merits are investigated by a higher authority.

Obituary

W. G. SYM, M.D., F.R.C.S.ED.

Consulting Ophthalmic Surgeon, Edinburgh Royal Infirmary

The death occurred on January 19 of Dr. William George Sym, emeritus lecturer on diseases of the eye in the University of Edinburgh. Dr. Sym was born at Edinburgh in 1864, and after a medical course at Edinburgh University graduated M.B., C.M. in 1886. He had already begun to take a special interest in ophthalmology, and decided to devote his professional life to this specialty. In 1889 he took the degree of M.D., and in the same year became a Fellow of the Royal College of Surgeons of Edinburgh. He held numerous appointments; such as ophthalmic surgeon to Leith Hospital, to the Eye, Ear, and Throat Hospital at Cambridge Street, Edinburgh; and in 1890 was appointed assistant ophthalmic surgeon to the Royal Infirmary of Edinburgh, becoming ophthalmic surgeon-in-ordinary in 1905. He relinquished this post in 1920 after the usual period of fifteen years, when he was appointed consulting ophthalmic surgeon to the institution. He was also for some fifteen years consulting ophthalmologist to the Scottish Command of the Army. He was a Fellow of the Ophthalmological Society, and for some years acted as editor of the *Ophthalmic Review*. He was the author of a well-known textbook on *Diseases and Injuries of the Eye*, published in 1913, and translator of the English edition of Adams's *Handbook of Treatment for Diseases of the Eye*. He also contributed many papers to periodical literature on subjects dealing with his specialty, such as "Simple Rules for Determining the Ocular Muscle Paralyzed," *Edinburgh Medical Journal*, 1898. As a clinician and teacher he was specially distinguished as a careful observer, a skilful operator, and a lucid lecturer and demonstrator. He enjoyed great popularity as a consultant and had a large ophthalmic practice. For three years he was a member of the Ophthalmic Committee of the British Medical Association.

In addition to professional activities Dr. Sym took a wide interest in public work, and was a member of many boards and public bodies. Among others he was a governor of Donaldson's Hospital, John Watson's Institu-

EPIDEMIOLOGICAL NOTES

Typhoid Fever

Croydon Outbreak.—There have been no fresh cases of typhoid fever since January 1, and the total notifications are 290. This number is exclusive of 5 nurses who have contracted the disease from contact with patients, three of them since January 1. The death on January 25 of a patient who contracted the disease eleven weeks ago brings the total number of deaths to 41.

Dysentery

The dysentery notifications for England and Wales have shown an appreciable increase over last week—280 cases against 256—while a proportionate increase has been encountered in London—65 notifications against 58 in the previous week. There have been 30 additional cases of Sonne dysentery notified in Bedford since last week, when 70 cases were notified in one day. As the milk supply is being either pasteurized or boiled it is probable that the majority of the notifications are contact cases.

Measles

Measles continues to spread in the principal large cities of the British Isles, particularly in Glasgow, in which the number of cases rose to 1,409, an increase of 608 on the previous week, while in Edinburgh the number notified was 327, as against 135 for the previous week. In Belfast, while the number of cases notified decreased from 592 to 567, the number of patients with measles in the Belfast Union Hospital rose from 154 to 176. The increase of admissions has severely taxed the accommodation at the Belfast Union Hospital. In London the expected measles epidemic is appearing more slowly than was anticipated. The number of cases admitted daily to the hospitals of the London County Council has risen during the week from some 20 to 30 admissions per day. While the Council has ample hospital accommodation at its disposal, it has found difficulty in securing a sufficient number of experienced nurses to staff its fever hospitals; as a result it has decided to place a restriction on the admission of infectious diseases, with the exception of diphtheria, to severe or complicated cases, or cases in which domiciliary treatment is for any reason deemed unsuitable.

Medical News

The Princess Royal will open the new extension to the Institute of Ray Therapy, Camden Road, N.W., on Saturday, February 5, at 3 p.m. Lord Horder will preside.

The following lectures will be given at the Royal Institution, 21, Albemarle Street, London, W., at 5.15 p.m., Tuesdays. February 1, 8, and 15, Professor J. D. Bernal, F.R.S., "Molecular Architecture of Biological Systems"; Thursday, February 3, Dr. E. J. Salisbury, F.R.S., "The Film in Biology: Plant Life"; Thursday, February 10, Mr. H. R. Hewer, "The Film in Biology: Embryology"; Friday, February 18, Professor E. N. da C. Andrade, D.Sc., F.R.S., "Science in the Seventeenth Century"; Thursdays, March 10, 17, 24, and 31, Sir Frederick Keeble, F.R.S., "The Fertility of the Earth."

A debate on the motion "That the Law on Abortion Requires Reform" has been arranged by the Fellowship of Medicine to take place at 1, Wimpole Street, W., on Wednesday, February 9, at 8.30 p.m. Sir Beckwith Whitehouse will propose the motion, and Dr. W. H. F. Oxley will oppose it. A discussion will follow. The chair will be taken by Mr. Justice Humphreys. The meeting is open only to members of the medical profession and the Medico-Legal Society, and admission will be by ticket obtainable from the Fellowship, 1, Wimpole Street, W.1.

A discussion on "The Ministry of Health New Model Building By-laws" will take place at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W., on Tuesday, February 8, at 5.30 p.m.

The annual general meeting of the Institute of Hospital Almoners will be held at 6 p.m. on Friday, February 4, at the Westminster Palace Rooms, 44, Victoria Street, S.W., when Dr. Henry Yellowlees will give an address entitled "Voluntary Social Service."

The next Réunion Médico-Chirurgicale de Morphologie will take place in Paris at the Maison de Santé Velpeau, 7, Rue de la Chaise, on February 9 at 9 p.m. The programme will include the presentation of a revue entitled "Physical Re-education" by Dr. Houdre of Paris. Dr. Marceron will speak on a morphopathological study of the motorist: M. Laville will discuss heredity in relation to morphology (with special reference to the laws of Lapouge); Drs. Chwatt of Lodz and Claoué, keloids and hypertrophic scars; Dr. Rochu-Méry, the morphology and morphogenesis of the abdomen; and Dr. Nepveu will make a communication on paraffin injections. These meetings are held at monthly intervals, and are open to all specialists in various branches of medicine and surgery who are interested in morphology. Further information may be obtained from Dr. Claoué, 39, Rue Scheffer, Paris XVIe.

With the object of encouraging original medical research, the Court of the Grocers' Company offers one scholarship each year tenable for two years of the value of £300 for the first year and of £450 for the second year. Candidates must be British subjects under 35 years of age. Applications must be made by the middle of April. Forms of application may be obtained from the Clerk of the Company, Grocers' Hall, Princes Street, London, E.C.2.

The address of the Westminster Hospital Medical School is now Horseferry Road, Westminster, S.W.1 (telephone number Victoria 6041). The change took effect on January 1.

The King has granted Professor R. S. Dobbin, of the Medical Faculty of the Egyptian University, authority to wear the Insignia of Grand Officer of the Order of the Nile, conferred upon him by the King of Egypt.

A quarterly periodical with the title *Zeitschrift für Altersforschung* is to be published by Theodor Steinkopff of Dresden and Leipzig. Edited by Professors Aberhalden and Burger, it will be concerned with the physiology and pathology of old age, and will correlate the many original articles on various aspects, including the zoological, veterinary, and biochemical, which are published throughout the world.

An illustrated pamphlet of twenty-four pages, *Medical Aid for Spain*, is published at 3d. by the Spanish Medical Aid Committee, 24, New Oxford Street, London, W.C.1. It gives a brief account of the arduous work carried out by units organized by this body, whose president is Lord Addison, chairman Dr. H. B. Morgan, and vice-chairman Mr. Somerville Hastings.

In the November number of the *Industrial Bulletin*, published by the State of New York Department of Labor, L. J. Goldwater discusses the pharmacology and toxicology of diethylene glycol, recently used with such tragic results as a vehicle for sulphanilamide in an American commercial preparation. Reference to poisoning by "elixir sulfanilamide" was made in the *British Medical Journal* of December 4, 1937, p. 1129. A series of articles on the subject has appeared in the *Journal of the American Medical Association* during recent months.

Professor C. G. Jung of Zurich will visit London early in April and will give four seminars at the Tavistock Clinic, Malet Place, W.C., which will be open only to medical practitioners. The titles of the seminars (subject to confirmation by Professor Jung) are: (1) Personal Factors in the Production of the Psychoneuroses; (2) Racial Factors in the Production of the Psychoneuroses; (3) Symbolism in Organic Disorders; and (4) Prophylaxis (Personal and Social) of the Psychoneuroses. In addition Professor Jung will give one lecture open to the general public, the title of which will be "Intuition and its Place in Science and Life."

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended January 15, 1938. Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 125 great towns (i) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns (ii) in Eire. (e) The 10 principal towns (iii) in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1938					1937 (Corresponding Week)					1928-36 (Median Value Corresponding Weeks)

* 567 cases in Belfast alone and 15 cases in Lisburn Urban District.

† All cases notified as puerperal pyrexia after October 1, 1937.

‡ Deaths from puerperal sepsis. § Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

82 Hereditary Factor in Essential Hypertension

E. A. HINES (*Ann. int. Med.*, October, 1937, p. 593) considers that the hereditary factor plays an important part in the aetiology of essential hypertension. In his investigations he used a "cold pressor test," which consisted in taking the blood pressure before, during, and after the immersion of the hand in water at 4° C. This test divides all persons into two groups: (1) those who have minimal or normal reactions; and (2) those who have excessive or abnormal reactions. Almost all persons with essential hypertension have abnormal reactions. One group of persons who do not show hypertension give excessive reactions to the cold pressor test as regards both diastolic and systolic pressure. They are called "hyper-reacting normals," and it is believed that they are in a pre-hypertensive stage and that many of them will eventually develop essential hypertension. A study has also been made of 608 individuals who had a normal blood pressure, and of 267 who had essential hypertension. A positive family history of hypertensive vascular disease is five times as frequent among individuals who have hypertension or who are hyper-reactors to a standard stimulus test as it is among individuals who react normally to the test. As no hyper-reactor was found who did not have one parent who was either hypertensive or a hyper-reactor it is probable that the trait is inherited as a dominant characteristic. The excessive or hypertensive type of reaction occurred predominantly among members of families in which there was a hypertensive diathesis. The inherited quality may affect the vasomotor system, which reacts excessively to certain external and internal stimuli to such an extent as to lead eventually to the development of essential hypertension in many cases.

83 Early Diagnosis of Renal Tuberculosis

G. PERKOVSKY (*Scalpel*, Liège, November 27, 1937, p. 1639) points out the difficulty of diagnosis in the early stages of renal tuberculosis. There may be no definite symptoms, and radiography is often of little assistance. It is suggested that the examination of the urinary deposit may provide the necessary proof of the disease. In this sediment, in cases of renal tuberculosis, two elements are found in association—pus and blood. Pus is usually present, and may be visible to the naked eye in cloudy urine; it is found in varying quantities in different cases. Red blood corpuscles are also present in the deposit; their number is usually less than that of the white cells, but the proportion does not vary greatly. When pyuria is accompanied by a small number of red cells, confirmed by repeated examination, a microscopical picture is given which is characteristic of renal tuberculosis. In all the cases submitted for examination this test has not failed in a single instance, and may serve as a useful base on which to establish an early diagnosis. It is suggested that this test should be carried out systematically on all urine submitted for investigation.

84 Prognosis of Peptic Ulcer

H. VENNDT (*Acta med. scand.*, 1937, 93, 3, 308) has investigated the after-histories of 421 patients who were admitted to the Bispebjerg Hospital in Copenhagen between 1923 and 1935, inclusive, for haematemesis or melaena due to gastric or duodenal ulceration. The strict dieting formerly enforced for the first two or three days has been relaxed since 1931 in favour of milk and oatmeal gruel from the first day, followed shortly by eggs, biscuits, toast, etc. Blood transfusion was performed in only sixteen severe cases, five of which terminated fatally.

There were approximately twice as many male as female cases, although there were twice as many beds available for men as for women. Of the twenty-five deaths in hospital, four were not due to the haemorrhage. In eighteen of the twenty-one cases coming to necropsy typical ulcers were found. In three cases gastritis was demonstrable. The seat of the ulceration was the stomach in twelve cases. Of the 396 patients leaving hospital alive, 327 were traced at the end of 1936. In the interval forty-six of the 396 had died, and the cause of death was recorded in forty-two cases, among which were eleven deaths notified as due to haematemesis, melaena, or gastric or duodenal ulcer. Six of the deaths were due to cancer of the digestive tract, and three to peritonitis which may or may not have been due to perforation of an ulcer. In one of the author's tables the frequency of the recurrence of haemorrhages from ulcers is calculated for each year after discharge from hospital, and he comes to the conclusion that in this respect 43 per cent. of his patients relapsed at some time or other within six years of discharge.

Surgery

85 Paraffinoplasty and Paraffinomata

C. CLAOUÉ and L. CHWATT (*Réun. méd.-chir. Morphologie*, March, 1937, p. 273) describe the technique of paraffinoplasty and point out the complications that may follow. This method of treatment is used to replace bone, cartilage, or fat where there has been loss of tissue. The paraffin is injected subcutaneously in a semi-fluid form, which later solidifies and remains at body heat. After sterilization of the operative field the syringe is inserted into the cellular tissue. A small quantity of warm sterile water is first injected to prevent the premature solidification of the paraffin, which should be about 60° C. at the time of injection. The important points of technique are that the paraffin should not be fluid but semi-fluid; that no more than 2 c.cm. should be injected at a time; that large vessels should be avoided; and that after injection has taken place the patient should stay in bed for twenty-four hours and in one room for a further one or two days, with applications of wet boracic compresses to the part injected. There are several variations of this method, some of them more complicated than that described. Although paraffinoplasty is attractive because of its simplicity it may be attended by either immediate or late complications. The most serious immediate complications may be an arterial embolus or phlebitis. Late complications may occur one, two, four, or even twelve years after treatment and take the form of tumours, which develop slowly but progressively and are called paraffinomata. These are usually subcutaneous, and may be either solitary or multiple. These nodules are hard and painless on palpation in the first stage, but later become fixed, lose their outline, and invade the deeper tissues. Functional disorders and pain develop later. Metastases may occur through the lymphatics, and may be found at some distance from the primary lesions.

86 Anal Fissure

P. C. BLAISDELL (*Surg. Gynec. Obstet.*, November, 1937, p. 672) points out that although anal fissure is a lesion of minor pathological import yet its frequency and the great discomfort it causes render it one of the most important of anal lesions. These fissures, which cause intense pain, are usually found placed directly posteriorly in the anal canal, and only occasionally directly anteriorly. This is perhaps due to the Y-shaped divergence of certain of the external sphincter fibres which are attached to the coccyx. The relatively weak and unsupported subcu-

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate "on MSS. if reprints are required, as proofs are not sent abroad."

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE BRITISH MEDICAL JOURNAL, Attitology
Westcent, London.

SECRETARY, *Medisecra Westcent, London.*
The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

"Cracking Skin"

Dr. A. E. MOORE (Histon, Cambs) writes: A patient of mine suffers from cracking of the skin of the hands and feet. As a girl she suffered from a cracked heel, and for the past twenty years both hands and feet have been affected. I should be glad of any help in diagnosis and treatment.

After-treatment of Circumcision

"A.B.C." writes: An elderly patient of mine had a circumcision performed some months ago. The glans is still tender and sensitive, especially about the corona. I should like suggestions for treatment.

A Case for Diagnosis

"PERPLEXED" writes: A patient of mine, a lady of 74, who has always been active and healthy, has for the last two months been subject to peculiar "attacks" recurring every day, sometimes after meals and sometimes when in bed. They vary in intensity, but only last for a minute or so. The pulse rate is slightly raised during the attack, which starts with the feeling of "a wave passing from the feet to the head." The skin of the cheeks is somewhat flushed and actually raised in patches for a few seconds, but it quickly fades. The patient feels quite well after the attacks. The blood pressure is 130 mm. Hg; the urine is normal, and so are the heart sounds.

The Squatting Position in Defaecation

Dr. J. H. BADCOCK (Bury St. Edmunds) writes: No one who has adopted the squatting position can have any doubt of its usefulness. To adapt the ordinary closet all that is needed is a light movable footstool about 18 inches by 6 inches, and of the required height. An upturned box, with a hole cut in the bottom for easy handling, answers perfectly. This is better for the aged or infirm than a low seat.

Dr. J. R. WHITWELL (London, W.1) writes: Many years ago I installed in my house one of Messrs. Doulton's "health closets." The result was so satisfactory that I felt compelled to say *Ruraliter in (com)modo sed fortiter in re.*

Hair Dye

Dr. HENRY J. KINGSLEY (London), in reply to "G.P.'s" question asking for a reliable dye for grey hair (*Journal*, January 22, p. 213), writes: I should recommend a bismuth preparation such as "entrupal" or "restorene," which both may be obtained from John Bell and Croyden Ltd. in

London. The effect of these bismuth preparations on the hair is due to the interaction of the bismuth with the complex sulphur molecule of the hair keratin.

LETTERS, NOTES, ETC.

Rehabilitation Centres for Injured Workmen

Mr. GILBERT G. PANTER (secretary, Royal Northern Hospital) writes: Dr. Eastwood, in his letter published in the *Journal* of January 22 (p. 202), with reference to the good work which is being done by fracture clinics, asks where can existing fracture clinics be found. I should like to say that the Royal Northern Hospital, which is one of the hospitals dealing with a very large number of fracture cases, has established at Holloway a whole-time fracture clinic and follow-up system for the benefit of fracture cases, particularly those involved in road traffic and industrial accidents.

Conservative Treatment in Oral Infection

Mr. J. H. OLVER, L.D.S. (London, W.1) writes: Oral sepsis is so often associated with rheumatic conditions that the mouth and throat are probably the first to be suspected. It is recognized now, however, that the most drastic methods may not be attended always with success; and also that, when this happens, the patient is apt to forget the pains-taking nature of the attempts to relieve him and regret the loss of teeth which were more practical in use than the artificial substitutes. Deepening of the gingival trough and "pocketing" can, of course, produce a considerable amount of septic absorption. Extraction will cure it, but less drastic methods will produce the same result unless the teeth are loosened. Gingivectomy is almost as unwarranted as extraction. A dressing which destroys the unhealthy epithelium and stimulates renewal of the lost tissue under conditions which are more favourable to a normal state is available, and has been used successfully for years. The dressing which I have found most effective for this purpose is liquor cresol. sap. It is, of course, necessary to apply it with great care, using cotton or bibulous paper dressings of an appropriate size saturated with the drug. The dressings are inserted into the pockets, etc., all other and surrounding parts being carefully isolated and a saliva ejector used. The length of time the dressing is allowed to remain in contact with the part varies, but from one to five minutes is generally sufficient. When the affected surfaces are definitely whitened the dressing is removed, some sedative, such as phenol-camphor, applied, and the whole of the treated surfaces thoroughly irrigated with an atomizer. No massage must be attempted immediately after this treatment has been started, and the dressing should not be renewed until from six to ten days have elapsed. It is generally necessary to repeat the dressing three times, except in obstinate cases, which may require more extended treatment. When the gums no longer bleed readily and the surface is free from the glazed appearance one often sees in these cases, massage (lightly at first) with a rubber bristle brush, using an alcoholic mouth-wash, will help to keep the parts in a normal condition. It should, of course, be pointed out that very thorough removal of all exciting causes, such as calcific deposits, overhanging fillings, crown hands, etc., should be carried out either before, or a week following, the first dressing.

The Medical Directory—A Warning

MESSRS. J. and A. CHURCHILL, Ltd., write: We wish to warn medical practitioners, particularly in the neighbourhood of Edinburgh, against a man who is visiting doctors' houses and who asks for the revision of a slip giving details of name, address, etc. He states that this information is required for the *Medical Directory*, and at the same time asks for some payment to be made to him. No charge is made for the insertion of name, address, qualifications, etc., in our directory, and therefore no person has our authority for making such a request. We shall be grateful for any information that will enable us to put an end to the activities of this individual.

Disclaimer

Dr. DONALD H. ISAAC writes to disclaim any responsibility for paragraphs in daily papers, and a placard in the town of Port Talbot, giving objectionable publicity to an operation performed by him.

It has not been found in any other condition or in normal persons. The excretion of this acid is the essential biochemical feature of the disease, and from experiments conducted by Jervis phenylalanine appears to be the main, if not the only, source of the phenylpyruvic acid. It is not yet known whether phenylpyruvic acid is a normal or abnormal stage in the oxidation of phenylalanine, nor whether the metabolic error is simply associated with the mental defect or is causal. These questions are discussed.

92 Neurological Effects of Vitamin Deficiency

H. M. ZIMMERMAN (*Schweiz. Arch. Neurol. Psychiat.*, 1937; 39, 7, 195) describes the nervous symptoms and histological changes produced by experimental deficiency of vitamins A, B₁, and B₂. White rats after forty to ninety days on a diet deficient in vitamin A developed general muscular weakness, disturbances of co-ordination, and paralysis of the hind limbs. Histologically, myelin degeneration in the sciatic nerves and the posterior roots, and Marchi degeneration in the posterior columns and around the periphery of the cord, were found. The administration of vitamin A may prevent death, but does not lead to cure of the nervous condition. In dogs with vitamin B₁ deficiency, after sixty to ninety days there occurred dragging and ataxia of the hind limbs. Later there were clonic spasms of the general musculature, which alternated with periods of flaccidity; death took place one to eight days after the onset of such spasms. Extensive myelin degeneration was seen in the peripheral nerves, but no definite changes were found in the cerebral nervous system. Administration of vitamin B₁ produced a quick recovery even in moribund animals. In growing dogs on an artificial diet containing all the necessary food factors except vitamin B₂, there gradually developed loss of weight, vomiting and diarrhoea, and pronounced muscle weakness, with death in 200 to 300 days. Marked myelin degeneration of the peripheral nerves, nerve roots, and the posterior column of the spinal cord with glial increase was noted. It is not stated definitely but seems to be inferred that the administration of vitamin B₂ leads to recovery of the animals. The changes are considered very similar to the nervous lesions of pellagra. Some questions in reference to this disease and Goldberger's "black-tongue" in dogs are discussed.

93 Carotid Sinus Syncope

A. S. FREEDBERG and H. SLOAN LEROY (*Arch. Neurol. Psychiat.*, Chicago, October, 1937, p. 761) describe four cases in which spontaneous attacks of syncope and convulsions were associated with an abnormal response to mechanical stimulation of the carotid sinus. A male, aged 56, suffered for six weeks from spells of weakness, fainting, and occasional loss of consciousness with convulsions, all occurring in the erect posture. Momentary pressure on the right carotid sinus, or more strenuous pressure on the left, constantly produced pallor of the face, a slight increase in the respiration rate, and loss of consciousness, followed in eight seconds by convulsions and incontinence of urine and faeces. The blood pressure dropped to a low level, and the heart showed a slowing of twelve beats a minute during the seizure. A tight bandage placed on the legs and abdomen raised the blood pressure but caused symptoms of weakness which soon passed off, however. Atropine and ephedrine had no effect on the attacks, but 1 c.cm. of 1 in 1,000 adrenaline injected subcutaneously prevented their induction. The injection of procaine around the sinus had a similar effect, and after denervation of the right carotid sinus there were no spontaneous attacks over a period of five months' observation. The second case, a male aged 65, was very similar. In the third case, again a male aged 65, pressure on the right carotid sinus produced loss of consciousness without convulsions, but always associated with a rise

of blood pressure of from 10 to 15 mm. Hg. The fourth patient, a female aged 63, suffered for fourteen months from attacks of faintness and unconsciousness occurring in the erect posture. A lymphosarcoma was removed from the right side of the neck, and following this the patient had a series of generalized epileptiform convulsions. Pressure on the right carotid sinus produced no symptoms or change in blood pressure and pulse, but pressure on the left sinus produced weakness and faintness with slowing of the heart and a fall of blood pressure. Weiss and others have divided syncope arising from disturbances of the carotid sinus into three groups: cerebral, cardiac, and vasomotor. The third case obviously falls into the cerebral group, but the mechanism of the production of the attacks is not known. In the cardiac and vasomotor types also it is not by any means certain that the alteration in cardiac action is the sole cause of the attacks. The differentiation of the cases from epilepsy is easy because the attacks generally occur in the erect posture, and mechanical pressure on the carotid sinuses always produces in some degree symptoms similar to those described by the patient. Treatment consists in dealing with any local pathological conditions together with denervation of the sinus.

94 Berner's Haemorrhages into the Fourth Ventricle

B. DAHL (*Norsk. Mag. Laegevidensk.*, November, 1937, p. 1347) has conducted post-mortem examinations and animal experiments with special reference to the observations of O. Berner, whose systematic studies of the floor of the fourth ventricle in fatal cases of head injuries and certain other non-traumatic cases have revealed haemorrhages in this part of the brain. Berner identified these haemorrhages with those evoked many years ago in experimental animals by Duret. Dahl's post-mortem material consists of some fifty cases in which the cause of death was not trauma. After describing the technique of his examination of the brain, he notes that haemorrhages were the rule rather than the exception in the fourth ventricle. Similar haemorrhages were also demonstrable on the surface of the brain in many cases. Discussing these findings and those of his animal experiments, he draws attention to the great medico-legal interest attaching to the mechanism of these haemorrhages. He comes to the conclusion that, whether death is due to an injury to the head or not, agonal haemorrhages can almost invariably be demonstrated on and in the brain if carefully sought. The demonstration of haemorrhages in the fourth ventricle (Berner's haemorrhages) do not therefore justify any conclusion which associates death with some alleged injury to the head. Dahl also believes that Berner's and Duret's haemorrhages differ from each other in their position, their appearance, and their origin.

95 Fatal Herniation of Cerebral Tumours

PAUL VAN GEHUCHTEN (*L'Encéphale*, September-October, 1937, p. 113) discusses the cause of death in some cases of cerebral tumour which result in herniation of the medial part of the temporal lobe into the posterior fossa. This herniation presses on the cerebral peduncle and the upper part of the pons, and it is this pressure which causes death. In six cases, five of temporal lobe tumours and one of an occipital lobe tumour, in which such herniation was present, death occurred suddenly—once after lumbar puncture, twice after ventriculography, twice after decompression, and in one case three months after decompression. In all these cases there were found in the peduncle and pons haemorrhages of various sizes around the arteries and arterioles. These haemorrhages do not arise by rupture of the vessels but by the fusion of foci of erythrodiapedesis around the vessels. If such lesions are extensive enough death follows rapidly. The mechanism of the production of the haemorrhagic foci, which are secondary to local alterations in pressure, is discussed.

taneous external sphincter with its overlying mucous membrane constitutes the point most vulnerable to injury during defaecation of the whole anal canal. Fissures usually occur so near the outlet that they may often be seen with very slight parting of the anal folds or outward sliding of the skin. Treatment should be directed to the severance of the muscle bar to conform with the Y-shape of the more superficial portion of the external sphincter, a light pack of vaseline gauze being laid in the wound in the direction of the anal canal for several days to prevent bridging instead of healing from below. In many hundreds of cases a wedge-shaped resection of the ulcer has been carried out with the broad base on the outside of the canal, including healthy tissue. The muscle bar is severed to prevent recurrence. The base of the wound must be prevented from healing before the apex, scar tissue must be removed and the edges of the wound carefully trimmed.

87 Traumatic Stricture of the Urethra

K. H. WANG and C. Y. CHAN (*Chin. med. J.*, November, 1937, p. 623) state that this condition is commoner in China than elsewhere owing to neglect and improper management of the ruptured urethra. They review the cases of thirty-eight patients suffering from this form of stricture treated in the Peiping Union Medical College Hospital within the past fifteen years; 19.5 per cent. of all urethral strictures seen during this period were traumatic in origin. The type of injury determines the site of the rupture and subsequent stricture. Falling astride a plank usually causes an injury of the bulbous urethra by driving it against the pubic arch. When the pelvis is fractured it is the membranous portion of the urethra which is invariably damaged. Traumatic stricture is characterized by its rapid development and its resistance to dilatation; 97.4 per cent. of the patients developed stricture within three months of injury, and in no instance could the stricture be dilated. Operative treatment consisted of resection of the stricture, end-to-end anastomosis, and external urethrostomy proximal to the anastomosis. If the stricture involves the posterior part of the membranous urethra or the prostatic urethra, this technique is not possible. In those cases a suprapubic cystostomy is necessary for retrograde sounding and location of the stricture or for diversion of the urinary stream post-operatively. Complete resection may not be possible, only the central portion of the stricture being rimmed out and the newly formed tunnel maintained by an indwelling catheter until epithelization has taken place. Of the seventeen patients who were followed up 75 per cent. showed excellent results, 18.8 per cent. fair results, and 7.2 per cent. unsatisfactory results.

Therapeutics

88 Pneumonia

R. HABERKORN (*Münch. med. Wschr.*, December 3, 1937, p. 1934) analyses 621 cases of pneumonia treated at Ludwigshafen; the mortality was 21.4 per cent. Cases of bronchopneumonia were excluded, with the exception of a few cases affecting at least one lobe in children and having similar clinical and radiological signs to those of croupous pneumonia. Among general therapeutic measures rest, narcotics for pain, and fresh-air treatment are regarded as most important, the last chiefly in children. Special treatment consisted in the administration of quinine or quinine and calcium. A group of 341 cases receiving quinine (usually quinine-urethane) in doses of about 0.5 gramme daily had 19.4 per cent. of deaths as compared with 11.5 per cent. in seventy-eight patients receiving combined treatment by quinine and calcium injected intramuscularly; small doses at frequent intervals

were preferred. The fall of temperature is by lysis rather than crisis, but the mean duration of the illness is not curtailed. Quinine treatment is not suitable for children; in adults its effectiveness depends on the earliness with which it can be instituted. In treatment of the associated circulatory embarrassment digitalis was found ineffective, as were salines injected intravenously. Importance is attached to injections of strophanthin on the appearance of early signs of circulatory failure—it is combined with calcium and its administration is preceded, in the presence of dyspnoea and cyanosis, by venesection.

89 Treatment of Threadworms

A. CASTELLANOS, A. V. PAUSSA, and J. P. TRUJILLO (*Bol. Soc. cubana Pediatr.*, October, 1937, p. 425), who record twenty-four illustrative cases, maintain that the citrate of iron and ammonia in large doses—amounting to 6 to 8 grammes in all—two or three times a day is well borne by children, and in such amounts has a destructive action on threadworms. Some cases, however, prove refractory, and it is impossible to say if they can be sterilized by larger doses, such as 5 to 12 grammes, for example. The drug is also very effective when given in enema which enable it to reach the caecum.

90 Erysipelas

É. SZEP (*Wien. klin. Wschr.*, November 26, 1937, p. 1617) assumes that in the majority of cases erysipelas is caused by streptococci, and only exceptionally by other micro-organisms, such as staphylococci and pneumococci. Up till recently he relied mainly on convalescent serum in the treatment of erysipelas, but lately he tried prontosil in a series of seventy-four cases with good results. In a number of cases the therapeutic results were improved by giving prontosil and quinine on alternate days (0.3 gramme of quinine three times a day). In severe cases the author found the combination of prontosil and convalescent serum beneficial. The mechanism of the action of prontosil is uncertain, it being still undecided whether prontosil acts by virtue of its particular affinity to the streptococcus (parasitotropic action) or through the reticulo-endothelial system in the same way as salvarsan.

Neurology

91 Excretion of Phenylpyruvic Acid

G. A. JERVIS (*Arch. Neurol. Psychiat.*, Chicago, November, 1937, p. 944) describes the results of an introductory study of fifty-six cases of mental deficiency (thirty male and twenty-six female) associated with the excretion of phenylpyruvic acid. Forty-two cases were found among 8,043 inmates of an institution for mental defectives, and its possible incidence among the general population is 0.004 per cent., which approximates fairly closely to that for other inborn errors of metabolism. The condition appears to be congenital, and no other aetiological factors were found. None of the patients were Jews; the ages of the patients varied from 2 to 58 with an average age of 21. The genetic data seemed to indicate that the condition is determined by a single recessive gene substitution. Clinically the patients were normally developed and often attractive, but they tended to be slightly microcephalic. Diffuse patches of eczema were found in half the cases. Neurological signs consisting of increase of muscle tone, extrapyramidal in type, tremor of the outstretched arms, and exaggeration of the deep reflexes were present in the majority of the cases. Phenylpyruvic acid was not found in the cerebrospinal fluid. Encephalograms made in eleven cases seemed to indicate a slight degree of diffuse cortical atrophy; 71 per cent. of the cases were idiots and 29 per cent. imbeciles. Phenylpyruvic acid was found in the urine of all the cases.

MENFORMON TABLETS

to reverse
menopausal changes

"I cannot refrain from mentioning the treatment of the MENOPAUSAL SYNDROME with œstrin. Quite small quantities of œstrin by mouth (1,000 to 5,000 units) are usually sufficient to control the hot flushes, headaches and dizziness, and to induce a remarkable feeling of well-being; and rather larger doses have a miraculous effect on such sequelae as pruritus vulvae, atrophic senile vaginitis, vaginal ulceration and kraurosis."

Obstetrics and Gynaecology

96

Cervical Pregnancy

A. SCHÜRGER (*Zbl. Gynäk.*, November 6, 1937, p. 2584) describes a rare form of extra-uterine pregnancy—namely, cervical pregnancy, of which not more than thirty instances have been recorded in the literature. Implantation of the ovum in the uterus depends on transmission of the ovum from the ovary to the uterus, a certain degree of maturation of the impregnated ovum taking place during the process. Cervical implantation is due to an increased rate of transmission or to slowing up of the maturation process in the ovum. In cervical pregnancy the ovum lies in the cervix, and the placenta is partly in the cervix, partly in the uterus. It occurs most often in multipara, a wide internal os being the predisposing factor. The cervix hypertrophies as pregnancy advances and the internal and external os disappear. The cervix is ballooned out and the external os can only be recognized as a small notch. The uterus can be felt like a cap over the soft ballooned-out tissue and feels like a haematometra. On inspection the os is livid and the vaginal veins greatly enlarged. The course of cervical pregnancy varies. The patient usually aborts during the first month. Frequently the ovum ruptures into the vagina, pouch of Douglas, or abdomen. A cervical pregnancy reaching the seventh month has been recorded. The prognosis is always grave; intractable haemorrhage, rupture, and sepsis account for 45 per cent. of fatal cases. Haemorrhage is always serious, and the more so when pregnancy is advanced. Compression of the aorta or clamping of the uterine blood vessels may save life temporarily. Total hysterectomy is indicated in advanced cases. In early cases resection of the cervical sac and mass ligation may be of value.

97

Bone-marrow in Pregnancy

F. RUSSO (*Ann. Ostet. Ginec.*, October 31, 1937, p. 1169) has made a special study of the bone-marrow in pregnant women. He used the sternal puncture method, and gives differential counts of the cells obtained in this way in twenty cases. An outstanding feature is the marked increase in immature red cells; in his series of cases these amounted to from 31 to 50 per cent. There was also some degree of eosinophilia; no true leucocytosis was observed. The total number of white cells was increased, but this would appear to be relative to the often large increase in the number of red cells. This erythroblastic reaction in the bone-marrow in pregnancy is quite definite, though not absolutely characteristic. Various theories have been put forward to explain it, and Russo inclines to the view that it is due to the influence of the maternal and foetal hormones on blood formation.

98

Hysteropexy for Genital Prolapse

R. LEBOVICI and B. Y. YOVANOVITCH (*Rev. Chir.*, Paris, October, 1937, p. 582) enumerate the various methods of treatment in use in cases of genital prolapse: colpoperineorrhaphy for young women when the prolapse is partial or complete, perhaps followed by ligamentopexy when retroversion is present; colpoperineorrhaphy alone or associated with direct hysteropexy in women nearing the menopause; and colpoperineorrhaphy or colpohysterectomy in old women. It is urged, however, that direct hysteropexy alone is a more satisfactory procedure. It is a safe and effective operation which has no adverse effect on conception, pregnancy, or delivery. A case is fully described in which hysteropexy was carried out in a woman of 34 for sterility and uterine retroversion. Three months after the operation pain had disappeared, the patient had gained considerably in weight, and the uterus was in a satisfactory position. Two years later the patient became pregnant, and gave birth to a child after a somewhat difficult labour. Three further cases are fully described in which retroversion of the uterus was treated by high fixation during pregnancy. In the first instance

appendicectomy was also carried out, and the patient went to term and was delivered normally, as were also the other cases. Hysteropexy is advocated in cases of genital prolapse in young women and in those who have passed the menopause. In every case so treated the mechanical result has been good and the uterus has been fixed permanently in the correct position, giving a sensation of pelvic security. Through a median abdominal incision the uterus is suspended by means of linen or silk threads, and fixed to the abdominal wall as high as possible. The fundus should reach the umbilicus. Nineteen cases of prolapse are reported, in all of which the result after operation was good.

Pathology

99 Morphology of Duodenal Perforation

H. TAMMANN and H.-H. LUDEWIG (*Zbl. Chir.*, December 4, 1937, p. 2769) have investigated histologically eight cases of perforated duodenal ulcer. All the cases but one had a history of ulcer of some duration; all the ulcers were situated in the anterior wall of the duodenal cap near the pylorus. The anatomical specimens were obtained immediately after the operation and fixed and treated in the usual way. A typical finding in all the cases was the pronounced inflammatory reaction in the wall of the perforation with numerous polymorphonuclear cells, few eosinophils, and exudation and hyperaemia. The presence of micro-organisms in the base of the ulcer seemed to favour the polymorphonuclear infiltration round the ulcer. Of the four layers typical of chronic ulcer described by Askanazy one—namely, the layer of granulation tissue—was never present. On the other hand, the authors were able to confirm the presence of a zone of oedematous connective tissue at the site of the perforation, as described by Puhl and Schmidt. Together with these authors they consider this zone of tumefaction of the connective tissue as a necrobiotic lesion of the tissues caused by the peptic action of the gastric contents.

100 Inhibitory Action of Iron on Tubercle Bacilli

R. DAVIES (*J. Path. Bact.*, 1937, 45, 3, 773) has studied the action of iron on the growth of the human tubercle bacillus. It was found by Henley that in a glycerinated broth medium the optimal concentration of iron was 0.003 to 0.008 per cent.; greater concentrations led to inhibition of growth. It was also stated by Loewenstein that haemoglobin was detrimental to the growth of the tubercle bacillus on an egg-containing medium. The present author used the simple medium described by Schwabacher, made up with two parts of egg yolk and one part of saline with sufficient glycerin to give a final concentration of about 5 per cent. This was the control medium. Similar batches of medium were prepared to which a known amount of ferrous ammonium sulphate or of rabbit haemoglobin was added. All tubes were inoculated with the same volume of a suspension of tubercle bacilli and incubated for twenty-eight days; the number of colonies developing was then counted. The control egg medium contained about 0.006 per cent. of iron; the ferrous ammonium sulphate medium had a total iron content of 0.017 per cent., and the haemoglobin medium a total iron content of 0.014 per cent. On both the experimental media there was considerable inhibition of growth, amounting to about 70 per cent. on the ferrous ammonium sulphate medium and to 100 per cent. on the haemoglobin medium, on which no growth occurred at all. It is possible that the inhibitory action of the haemoglobin may have been due in some measure to its method of preparation with xylol, since a control xylol medium had a 35 per cent. inhibitory effect on growth. The results, on the whole, seem to show that the addition of iron to an egg yolk medium interferes with its value for the growth of tubercle bacilli, and suggest that the inhibitory action of haemoglobin may be determined in whole or in part by its iron content.

Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil. Blaud. The iron content remains fresh and unoxidized indefinitely, and

injury to the teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.

FOR HIGH BLOOD PRESSURE

HIPANTHYCAL TROPELS (Regd.)

The employment of Hipanthycal is indicated for the reduction of arterial hypertension in cardio-vascular-renal disease, particularly arterio-sclerosis.

It definitely reduces high blood pressure, but not rapid enough to cause excessive hypotension. This is effected without any depressing effects on the patient.

Each tropel contains Pancreas Ext. 1½ gr., Thyroid B.P. 1932, 1/10 gr., Calf Liver Substance 1 gr., Ammonium Hippurate 1 gr., Sodium Hippurate 1 gr.

Price 5/- per bottle of 100; 250, 10/-; 1,000, 32/-

Literature on request.

WYLEYS LIMITED, MANUFACTURING CHEMISTS, COVENTRY. Established 1750.

Mild Constipation shown to yield to laxative effect of HOVIS

Many of the mild forms of constipation so prevalent to-day are attributed to the consumption of foods deficient in Vitamin 'B'. In comparing the effects of various kinds of bread it is seen that HOVIS germ bread is superior to either white bread or wholemeal in supplying this deficiency. Whilst white bread contains practically no Vitamin 'B', HOVIS, with its added

proportion of 25% wheat-germ, supplies an abundance of this essential food-element. Unlike wholemeal bread, HOVIS contains only a minute percentage of bran and indigestible cellulose. In other words its incorporation in the normal diet ensures not only a higher standard of nutrition but easier assimilation and regular evacuation of the intestinal contents.

VITAMIN 'B' CONTENT ACTS AS AID TO REGULARITY

Salt's
PATENT

Gastroptosis Belt

This belt, used in conjunction with suitable dietetic and medicinal measures, provides an eminently satisfactory method of correcting displaced abdominal viscera. A commendable feature is that the Belt in no way interferes with the proper functioning of the organs. Radiological examination has shown that it definitely retains the stomach in its proper position, whilst clinical experience has revealed the prompt and *continuous* relief of symptoms afforded by its use. Any doctor desirous of further information about this Belt has only to drop a line for a copy of Salt's Corset and Belt Book which will be sent post free per return.

VICHY-CÉLESTINS

THE WORLD-RENOWNED

FERMENTATIVE

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine,

NATURAL VICHY SALT for
Drinking and Baths.

NATURAL MINERAL WATER

DYSPEPSIA

become absorbed by the lymphatics and swept into the circulation. Vichy-Célestins, by its slightly stimulating action, clears out the stomach, and thus avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CURTIS - The Support that is prescribed by leading London Hospitals

The Curtis Abdominal Model No. 1 is the best method of supporting the lower abdomen without undue constriction. It is scientifically designed to give an even anterior-posterior pressure—at the same time allowing greater freedom to the hips. Model No. 1 is indicated in the treatment of all forms of abdominal ptosis-visceroptosis, enteroptosis and gastroptosis; and it is recommended for support of ventral hernia and scar tissue in the lower abdomen.

The problem of SURGICAL STOCKINGS

Doctors who prescribe Compri-Vena Stockings are sure that the most beneficial support is given as each one is made to the patient's measurements and needs. They have long been recommended for Varicose veins and in conjunction with Infection Treatment as well as during and after Pregnancy. They are also invaluable in relieving undue leg strain. Compri-Vena Stockings are rubberised and yet elastic, are washable, cool in wear and irremovable under ordinary silk stockings. They give real relief and preserve the shape of the legs. A skilled staff carefully follow all doctors' instructions. Full details from:

GAS-AIR ANALGESIA

The demand for a simple portable apparatus for the administration of N_2O and air mixture, has led to the production, by this company, of the "Queen Charlotte's" Gas-Air Analgesia Apparatus. Features of this apparatus are perfect safety, low cost, portability, compactness and simplicity. Models of this apparatus have been in successful use, day and night, at Queen Charlotte's Hospital during the past year. Practitioners are invited to apply for an illustrated booklet, describing the apparatus, and giving full particulars of prices.

The Convalescent Branch is HOVE VILLA, BRIGHTON, and is 200 feet above sea-level.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS

NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm gardens and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

EDINBURGH POSTAL COURSES.

Full details of above and Oral Courses at H.C. Green, F.R.C.S., Surgeon's Hall, Edinburgh.

ROYAL AIR FORCE MEDICAL SERVICE.

Applications are invited from medical men for appointment to commissions in the Medical Branch of the Royal Air Force for entry in May, 1938.

Candidates must be of pure European descent. They must be British Subjects, the sons of British Subjects and registered under the Medical Acts.

Candidates must normally be under 28 years of age but as a temporary measure consideration will be given to candidates up to 31 years of age and will be selected after interview by a selection board without competitive examination.

Hospital appointments held since qualifying will, under certain conditions, qualify candidates for antedate of commission up to a maximum of one year: the age on entry may, if necessary, be increased by a period equal to the "antedate."

Selected candidates will be appointed to short service commissions (for three years extendible to five years) followed by four years' service in the Reserve, and will be eligible to be considered for Permanent Commissions after having completed their first year of service and during the whole period of their service on the active list. Officers selected for Permanent Commissions will be allowed to count their service on a short service commission towards retired pay or gratuity to permanent officers. Officers not selected for Permanent Commissions receive gratuity as follows on transferring to the Reserve:—

On completion of three years, £400. On completion of five years, £1,000.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, also form of application, may be obtained on application from:—The Secretary, Air Ministry (D.M.S.), Adastral House, Kingsway, W.C. 2.

Completed applications from intending candidates for the vacancies in May, 1938, must be received in the Air Ministry not later than March 15th, 1938.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in April, 1938.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W. 1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than February 28th, 1938.

IRAQ GOVERNMENT.

APPOINTMENT OF BRITISH SURGICAL SPECIALISTS.

The Iraq Government invite applications from British Medical and Surgical Specialists (male) for the following vacant appointments.

1. OBSTETRICIAN AND GYNAECOLOGIST.

Duties: To be Professor of Obstetrics and Gynaecology in the Royal College of Medicine, Bagdad, and Chief of the Unit of Obstetrics and Gynaecology in the Royal Hospital, Bagdad.
Salary: Iraq Dinars 150 per mensem.

2. EAR, NOSE, AND THROAT SPECIALIST.

Duties: To be Lecturer on Ear, Nose, and Throat diseases in the Royal College of Medicine, Bagdad, and Chief of one of the Units for these diseases at the Royal Hospital, Bagdad.

Salary: Iraq Dinars 120 per mensem. In special circumstances if it is considered that the candidate's qualifications and experience justify it a salary in excess of this amount, but not exceeding 150 Dinars per mensem, may be granted.

3. GENERAL SURGICAL SPECIALIST.

Duties: To act as Surgical Specialist in any hospital of the Iraq Health Service as required and to assist in the teaching of Surgery in the Royal College of Medicine, Bagdad, if required.

Salary: Iraq Dinars. 120 per mensem.

Candidates must be experienced in operative work and must hold a Specialist's diploma in their branch of work, such as F.R.C.S., M.C.O.G., or D.L.O.

Age must not exceed 45 years. Successful candidates will be required to enter into contracts for a period of five years. Consultant practice is allowed provided that it does not interfere with the performance of official duties. The teaching at the Medical College is in the English language.

One Iraq Dinar is equivalent to one Pound Sterling. Salaries will be subject to Iraq Income Tax which is:—150 dinars exempt, the next 150 dinars subject to 6% tax, and the remainder of the income 9%.

Forms of application and copies of the Form of Contract can be obtained from the Iraq Minister, the Royal Iraq Legation, 22, Queen's Gate, London, S.W. 7. Particulars as to the Provident Fund, leave, and passage allowances are given in the Form of Contract.

No application can be considered unless received on the prescribed form not later than February 18th.

UNIVERSITY OF BIRMINGHAM

INGLEBY LECTURES, 1938.

The Dean and the Faculty of Medicine request the pleasure of the attendance of Members of the Medical Profession at THE INGLEBY LECTURES, on Thursdays, February 3rd and 10th, at 4 o'clock, in the Medical Lecture Theatre (Edmund Street Buildings) by LEONARD COLFURROCK, M.B., B.S. (London), (Director, Bernhard Baron Memorial Research Laboratories, Queen Charlotte's Hospital, London) Subject *The Control of Puerperal and other infections caused by Haemolytic Streptococci*. (The first Lecture will deal with preventive measures, the second with treatment by Sulphanilamide and allied drugs.)

UNIVERSITY OF ABERDEEN.

LECTURESHIP IN BACTERIOLOGY

The University Court will shortly proceed to the appointment of a Lecturer in Bacteriology in the University of Aberdeen.

The salary proposed is £500 to £600 according to qualifications and experience.

Persons desirous of being considered for the office are requested to lodge their names with the Secretary to the University on or before February 18th, 1938.

The conditions of appointment and form of application may be obtained from the undersigned.

H. J. BUTCHART.

Secretary to the University of Aberdeen
The University, Aberdeen

UNIVERSITY OF WALES

THE WELSH NATIONAL SCHOOL OF MEDICINE

Applications are invited for the DAVID DAVIES PROFESSORSHIP OF TUBERCULOSIS. The person appointed will also hold office as Director of Research and Honorary Consultant to the Welsh National Memorial Association. The appointment is a full-time one and the combined emoluments are at the rate of £1,500 per annum.

Further particulars of the appointment may be obtained from the Secretary, The Welsh National School of Medicine, The Parade, Cardiff.

S. C. EDWARDS
Secretary

THE ARMY DENTAL CORPS.

Applications are invited from dental surgeons for appointment to a limited number of commissions in The Army Dental Corps.

Candidates, who should not be over 28 years of age, will for the present be selected for commissions without competitive examination, but will be required to present themselves in London for interview and physical examination. They must hold the degree or diploma of a British University or College of Surgeons and be registered under the Dentists' Acts or Medical Acts.

Successful candidates will, in the first instance, be given short service commissions for six years, at the end of which period they will retire with a gratuity of £1,000, unless they have been granted permanent commissions. Permanent commissions will be given to officers selected from among those who wish to make the Army their permanent career.

Particulars, including Regulations for Admission, pay and allowances, and forms of application may be obtained on request either in writing or in person to the Director, Army Dental Service, The War Office, London, S.W.1.

ROYAL NAVAL DENTAL SERVICE

Vacancies exist for DENTAL OFFICERS in the ROYAL NAVY, and applications for entry are invited from Registered Dental Surgeons.

Candidates must be British subjects of pure European descent, below 28 years of age on the day of entry and physically fit for service in any part of the world. Unmarried candidates are preferred. Candidates will be required to attend at the Admiralty for physical examination and interview by a Selection Board.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of Dental Schools.

HARROGATE AND DISTRICT GENERAL HOSPITAL (132 Beds)

CASUALTY OFFICER AND HOUSE SURGEON TO SPECIAL DEPARTMENTS required at the above hospital for a period of six months from March 1st. Salary £150 p.a. plus full residential emoluments. Applications as soon as possible to the Secretary.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark Hill, S.E.5.

ADVANCED MEDICINE COURSE.

A COURSE in Clinical Medicine, Pathology, Morbid Histology and Bio-Chemistry, suitable for M.D. and M.R.C.P. EXAMINATIONS, will be given for seven weeks, commencing on FEBRUARY 16th.

The Class is limited in number. The next Course will be held from May to July.

UMTATA HOSPITAL BOARD.

SIR HENRY ELLIOT HOSPITAL

APPOINTMENT OF SENIOR RESIDENT MEDICAL OFFICER

Applications are invited from qualified Registered Medical Practitioners for the above-mentioned post. The salary attached to this position, which is whole-time, is at the rate of £600 per annum, plus for house, water, light and sanitation. A detached storied dwelling-house is shortly to be erected in which the successful applicant will be required to reside, but pending its completion he will be allowed an amount of £10 per month in lieu of quarters and incidental costs.

The successful applicant is to assume duty on July 1st, 1938, and to enter into contract of office for three years (which may be renewed), the first year to be on probation.

The Hospital has 154 beds (22 European, 132 Native), but this accommodation will be increased by approximately 60 beds in the near future. Duties include assisting at operations, anaesthetics, pathology, the general ward work of a resident medical officer, lecturing to nurses, and the general medical and surgical supervision of the whole Hospital.

Applicants to state full particulars of (1) Their Medical and, in particular, Postgraduate and Surgical experience.

(2) Nationality, age, and whether married or single.

(3) Whether fully conversant with both English and Afrikaans.

Applications, with copies of three recent medical and health certificates, must be lodged with the undersigned not later than 1st March 1938.

UMTATA C. F. REYAN
Cape Province, South Africa

BOROUGH OF EALING. **RESIDENT ASSISTANT MEDICAL OFFICER.**

Applications are invited from duly qualified medical men (male) with a Public Health qualification for the position of Resident Assistant Medical Officer. A candidate must have had experience in the treatment of cases of infectious disease at an Isolation Hospital. The duties will include the medical care of patients in the Chiswick and Ealing Isolation Hospital, South Ealing, and the medical inspection and treatment of school children at whom the health centres in the Borough of Ealing. The person appointed will reside at the Isolation Hospital, where furnished rooms and board will be provided. He will be required to devote his whole time to the duties, and will not be allowed to engage in private practice. The salary will be at the rate of £150 per annum, rising by £25 per annum to a maximum of £250, plus board and residence, as indicated above and valued at £150 per annum.

A deduction of 5 per cent. will be made from the salary in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the Council's medical examination in connection therewith. Canvassing will be a disqualification.

Copies of the application forms and terms of appointment can be obtained from Dr. THOMAS ORR, Medical Officer of Health, Town Hall, Ealing, W.S., to whom application, accompanied by copies of not more than three recent testimonials, must be delivered not later than February 10th.

Town Hall, R. H. WANKLYN, Town Clerk, Ealing, W.S.

BOROUGH OF EALING. **ASSISTANT MEDICAL OFFICER OF HEALTH.**

Applications are invited from duly qualified medical men with a Public Health qualification for the position of Assistant Medical Officer of Health. A candidate must have had at least three years' experience in the practice of his profession. The person appointed will be required to carry out medical inspection of school children and child welfare work, and perform such other duties as may be allotted as Assistant to the Medical Officer of Health and School Medical Officer.

He will be required to devote his whole time to the duties, and will not be allowed to engage in private practice. The salary will be at the rate of £600 per annum, rising by £25 per annum to £700.

A deduction of 5 per cent. will be made from the salary in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the Council's medical examination in connection therewith. Canvassing will be a disqualification.

Copies of the application forms and terms of appointment can be obtained from Dr. THOMAS ORR, Medical Officer of Health, Town Hall, Ealing, W.S., to whom application, accompanied by copies of not more than three recent testimonials, must be delivered not later than February 10th.

Town Hall, R. H. WANKLYN, Town Clerk, Ealing, W.S.

ADMINISTRATIVE COUNTY OF CAMBRIDGE. **DEPUTY MEDICAL OFFICER OF HEALTH.**

The Cambridgeshire County Council invite applications for the post of Deputy Medical Officer of Health for the County from duly qualified practitioners registered in the Medical Register as holders of a diploma in sanitary science, public health or State medicine.

The officer appointed will act under the direction of the Medical Officer of Health for the County (who is also School Medical Officer) in the general administration of public health and in other medical work of the Council, including that of the Education Authority. The duties will be mainly in connection with school medical inspection, and experience in refraction and diseases of the eye is essential. The officer appointed must not engage in private practice or hold any other appointment.

The salary attached to the post is £600 per annum, rising by increments of £50 to £750 per annum. A car will be provided or an allowance made for travelling, but there will be no subsistence allowance within the County.

The post is subject to superannuation, and the selected candidate will be required to undergo a medical examination. The appointment will be terminable by three months' notice in writing on either side.

A form of application (with any further information desired) can be obtained from the Clerk of the County Council by sending a stamped addressed footcap envelope. Applications must be received not later than February 25th, 1938.

Shire Hall, ASHLEY TABBRUM, Clerk of the Council, Castle Hill, Cambridge, January 25th, 1938.

GLOUCESTERSHIRE COUNTY COUNCIL. **DEPUTY COUNTY MEDICAL OFFICER OF HEALTH.**

Applications are invited for the appointment of Deputy County Medical Officer of Health (male) at a salary of £750 per annum. Travelling and subsistence allowances will be paid in accordance with the Council's scale.

The appointment will be a designated post for the purposes of the Local Government and Other Officers' Superannuation Act, 1922, and will be subject to a satisfactory report by the Council's medical adviser.

Applicants must be registered Medical Practitioners, should hold a Diploma in Public Health, and have experience in general public health duties and in the administrative work of a Public Health Department.

Forms of application, with particulars of the duties and conditions of appointment, may be obtained from the County Medical Officer of Health, Shire Hall, Gloucester, to whom completed applications, with copies of three recent testimonials, should be sent not later than February 14th, 1938.

Canvassing directly or indirectly will be a disqualification.

RICHARD L. MOON, Clerk of the County Council, Shire Hall, Gloucester.

GLOUCESTERSHIRE COUNTY COUNCIL. **ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.**

Applications are invited for the appointment of Assistant County Medical Officer of Health (male) at a salary of £500 per annum, rising by £25 per annum to £700 per annum. Travelling and subsistence allowances will be paid in accordance with the Council's scale.

The appointment will be a designated post for the purposes of the Local Government and Other Officers' Superannuation Act, 1922, and will be subject to a satisfactory report by the Council's medical adviser.

Applicants must be registered Medical Practitioners, and should hold a Diploma in Public Health. Previous experience in various branches of public health and school medical work is desirable.

Forms of application, with particulars of the duties and conditions of appointment, may be obtained from the County Medical Officer of Health, Shire Hall, Gloucester, to whom completed applications, with copies of three recent testimonials, should be sent not later than February 14th, 1938.

Canvassing directly or indirectly, will be a disqualification.

RICHARD L. MOON, Clerk of the County Council, Shire Hall, Gloucester.

BOROUGH OF FINCHLEY. **MATERNITY AND CHILD WELFARE.**

LADY ASSISTANT MEDICAL OFFICER (Part Time).

Applications are invited from duly registered women practitioners for the above appointment. Candidates must have at least three years' experience in the practice of their profession, and previous experience in the conduct of an Infant Welfare Centre is essential.

The duties will entail attendance at an Infant Welfare Centre during two weekly sessions of 2 hours each, for which a fee of 11 guineas per session will be paid.

The successful candidate will be required to take up her duties on April 1st, 1938.

Applications, together with copies of three recent testimonials, should be received by the Medical Officer of Health, 305, Regent's Park Road, N.3, not later than first post on Saturday, February 12th, 1938.

Principal Offices H. WOOD BARTER, Finchley, N.3, Town Clerk, January 25th, 1938.

COUNTY BOROUGH OF OLDHAM. **PUBLIC HEALTH DEPARTMENT.**

TEMPORARY ASSISTANT MEDICAL OFFICER.

Applications are invited from registered medical practitioners for the post of Temporary Assistant Medical Officer of Health for the County Borough of Oldham. The duties are mainly in connection with Diphtheria Immunisation, but the officer appointed will be required to undertake such other duties in the Department as the Medical Officer of Health may direct. He will be required to reside in the Borough.

The salary will be at the rate of £500 per annum.

Applications, stating age, and giving full particulars regarding training and qualifications, and appointment desired, should be forwarded to the Medical Officer of Health, Town Hall, Oldham, together with copies of three recent testimonials, so as to reach him not later than Tuesday, February 8th, 1938.

Town Hall, THOMAS ALKER, Town Clerk, Oldham, January 24th, 1938.

RURAL DISTRICT OF PONTARDAWE. **APPOINTMENT OF MEDICAL OFFICER OF HEALTH (Male).**

Applications are invited from duly qualified and registered Medical Practitioners who are also registered in the Medical Register as the holder of a Diploma in Sanitary Science, Public Health or State Medicine, for the post of Medical Officer of Health of the Rural District of Pontardawe. The appointment is subject to the provisions of the Local Government Act, 1933, the Sanitary Officers' (Outside London) Regulations, 1935, and the Local Government and Other Officers' Superannuation Act, 1922.

The person appointed will be required to perform all the duties imposed on a Medical Officer of Health under relevant Acts and Orders to undertake administration of the Maternity and Child Welfare Service, to act as Chief Medical Adviser to the Local Authority, and will also be required to carry out such other duties as the Council may, with the consent of the Ministry of Health (where necessary) from time to time direct.

The person appointed must reside within the Rural District, must not engage in private practice and must devote his whole time to the duties of the office.

The successful candidate will be required to furnish a satisfactory medical certificate in the form prescribed by the Council.

The salary will be at the rate of £500 per annum, plus £100 per annum as travelling allowance.

Clinical assistance and office accommodation will be provided by the Council.

Applications of the prescribed form, accompanied by not more than three recent testimonials, and endorsed "Appointment of Medical Officer of Health," must be delivered to the undersigned on or before February 15th, 1938.

COUNCIL OFFICES, PONTARDAWE, NEVILLE S. DAVIES, Clerk, January 25th, 1938.

METROPOLITAN BOROUGH OF GREENWICH. **APPOINTMENT OF A PUBLIC VACCINATOR.**

The Council of the above-named Borough is prepared to receive applications from properly qualified and experienced medical practitioners for the position of Public Vaccinator for that portion of the Borough of Greenwich which, immediately prior to March 31st, 1930, comprised and was known as the Parish of Charlton and Kidbrooke.

The appointment will be subject to the approval of the Ministry of Health and to the provisions of the Vaccination Order, 1920.

The successful applicant will be required to enter into a Contract for the due performance of the work, as provided by such Order, and to supply the name of a suitably qualified deputy to act as occasion may require in the absence of the candidate appointed.

Particulars of the Contract and of the fees payable may be inspected upon application to the undersigned during ordinary office hours.

Applications for the position, giving particulars of experience in the work of vaccination, must be sealed up and delivered to the office of the undersigned not later than 12 o'clock noon on Monday, February 14th, 1938.

Canvassing Members of the Council, either directly or indirectly, will be a disqualification.

Town Hall, D. J. REASON, Town Clerk, Greenwich, S.E.10, January 25th, 1938.

SURREY COUNTY COUNCIL. **MENTAL HOSPITALS COMMITTEE.**

APPOINTMENT OF JUNIOR ASSISTANT MEDICAL OFFICER (MALE).

Applications are invited for the post of male Junior Assistant Medical Officer (unmarried) in the Surrey County Council Mental Hospital Service.

Commencing salary, which will be subject to statutory deductions under the provisions of the Asylum Officers' Superannuation Act, 1909, will be £350, rising by annual increments of £25 to a maximum of £450 per annum, together with gratuities, board, laundry and attendance valued for superannuation purposes at £150 per annum. The person appointed will also be paid, in addition to his salary, the sum of £50 per annum if he holds the Diploma in Psychological Medicine.

The appointment will be subject to termination by one calendar month's notice on either side, and the person appointed will be required to undergo a medical examination.

Applications, stating age, accompanied by copies of three recent testimonials, and enclosed in an envelope endorsed "Mental Hospitals Junior Medical Officer," must reach me not later than Saturday, February 12th, 1938.

DUDLEY ARKLAND, Clerk of the Council, Mental Hospitals Department, County Hall, Kingston-upon-Thames, January 24th, 1938.

GLAMORGAN COUNTY COUNCIL. PUBLIC ASSISTANCE COMMITTEE.

LLWYNPIA HOSPITAL (Rhondda). APPOINTMENT OF RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners (male), under 35 years of age, for the appointment of Resident Assistant Medical Officer at Llwynpia Hospital (182 beds). The person appointed will be required to assist under the direction of the Medical Superintendent in the general work of the hospital, and should have had resident experience at a General Hospital. Post-graduate experience in ear, nose and throat surgery will be an additional advantage.

Salary £350 per annum, rising by £25 annually to £450 per annum, with residential emoluments valued for superannuation purposes at £75 per annum.

The appointment, which will be terminable by two months' notice on either side, is a designated post under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass an examination as to physical fitness.

Applications, stating age and qualifications, and accompanied by copies of not more than three recent testimonials, must be received by the County Medical Officer, Glamorgan County Hall, Cardiff, not later than the first post on Thursday, February 10th, 1938.

Glamorgan County Hall, HENRY ROWLAND,
Cardiff, Clerk of the County Council.
January 22nd, 1938.

COUNTY BOROUGH OF CROYDON. PUBLIC HEALTH DEPARTMENT.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER FOR OBSTETRICS.

Applications are invited from qualified medical men and women for the post of Assistant Medical Officer for Obstetrics. Candidates must have had practical hospital experience in Gynaecology and Obstetrics, and of ante-natal and post-natal clinics.

The appointment will be for twelve months, and the salary will be £350 per annum, with board, residence and laundry valued at £140 per annum. The successful candidate will have quarters at St. Mary's Hospital, St. James Road, Croydon.

Opportunities will be given for the successful candidate to study for the Membership of the College of Obstetricians and Gynaecologists.

The officer appointed will be on the staff of the Medical Officer of Health, and work under his administrative supervision.

Application forms may be obtained from the Medical Officer of Health, Town Hall, Croydon, on receipt of a stamped addressed foolscap envelope, and should be returned to him not later than 11 a.m. on Monday, February 7th, 1938, together with copies of three testimonials of recent date. Canvassing in any form is prohibited.

Town Hall, L. TABERNER,
Croydon, Town Clerk.
January 24th, 1938.

BOROUGH OF EDMONTON EDUCATION COMMITTEE.

ASSISTANT SCHOOL DENTAL SURGEON.

The Education Committee invite applications for the post of Assistant School Dental Surgeon. Applicants, who may be of either sex, should be fully qualified for the practice of dental surgery, and should be duly registered. Experience in school dentistry a recommendation.

Salary £450 per annum, rising by annual increments of £25 to a maximum of £600 per annum. The post is designated under the Local Government and Other Officers' Superannuation Act, 1922, and the salary will be subject to a deduction of 5 per cent in accordance with the provisions of that Act.

Application forms and further particulars may be obtained from the undersigned on receipt of a stamped addressed foolscap envelope. Applications should be returned not later than Saturday, February 12th, 1938.

Canvassing, either directly or indirectly, will be a disqualification.

Education Offices, W. L. BROWN,
Brettenham Road, Director and Secretary,
Edmonton N.15.
January 21st, 1938.

BOROUGH OF BARKING. PUBLIC HEALTH DEPARTMENT.

Applications are invited from Registered Dental Surgeons for the designated appointment of ASSISTANT DENTAL SURGEON.

Salary Scale £450-£600.
Particulars of duties and application form can be obtained from the undersigned, to whom all forms must be returned not later than first post on Saturday, February 12th, 1938.

Town Hall, S. A. HAWES,
Barking, Town Clerk.

COUNTY BOROUGH OF BLACKBURN.

LADY ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from duly registered women practitioners for the appointment of ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER to act under the direction and supervision of the Medical Officer of Health, who is also, School Medical Officer. The salary is at the rate of £600 per annum, rising by annual increments of £25 to £700 per annum.

The person appointed must have had at least three years' post-graduate experience in the practice of her profession and special experience of midwifery and ante-natal work. Special post-graduate experience in the treatment of venereal diseases of children, and the possession of a registrable degree or diploma in Public Health, will be deemed additional qualifications.

Applications to be made on forms to be obtained from the Medical Officer of Health, Victoria Street, Blackburn, and returned to him not later than Saturday, February 12th, 1938, endorsed "Assistant Medical Officer of Health."

Canvassing directly or indirectly will be a disqualification. CHAS. S. ROBINSON,

WEST LONDON HOSPITAL, Hammersmith, W.6. (239 Beds.)

Applications are invited for the post of **MEDICAL REGISTRAR** to the Children's Department for a period of one year, eligible for re-election annually for a total period of not more than three years. An honorarium at the rate of £100 a year is attached to the post.

The duties include attendance in the Out-Patient Department on four mornings a week, acting as deputy for the Physician to the Children's Department when required, and such teaching for the West London Hospital Medical School as the Board may approve.

Candidates, who may be male or female, must be registered under the Medical Act, and should have had wide experience in children's work.

Applications, with copies only of testimonials, should reach me not later than Thursday, February 17th. Candidates must attend the meeting of the Medical Council at 4.30 p.m. on Friday, February 18th, and prior to that date call upon and send copies of their application and testimonials to each member thereof. They must not canvass members of the Board, but nevertheless should send copies of their application and testimonials to each member thereof and, if so notified, be in attendance at a meeting of the Board at 5 p.m. on Tuesday, February 22nd, when the election will be made.

H. A. MADGE, Secretary.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London, W.C.1.

A **RESIDENT AURAL REGISTRAR** is required duties to commence not later than April 1st, 1938.

Gentlemen are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, February 21st, 1938, with copies of not more than three testimonials given specially for the purpose.

The appointment will be made for one year, but the holder may be re-elected for a further period of one year. Salary £150 per annum, laundry allowance £10, board and residence in the hospital. The duties will be those of a house officer to the Aural In-Patients, and of a registrar in assisting in the Aural Out-Patient Department. Opportunity will be afforded for acquiring operative experience.

Candidates must be unmarried and possess a legal qualification to practise, and must have held a responsible resident appointment at a General Hospital.

All candidates must be in attendance to appear before the Joint Committee, if required, at their meeting on Wednesday, March 2nd, 1938, at 4.45 p.m. precisely.

Forms of application and copies of the Rules can be obtained from the undersigned.

HERBERT F. RUTHERFORD,
January, 1938. Secretary.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London, W.C.1.

Applications are invited for the post of **ASSISTANT PATHOLOGIST** (male).

Candidates, who must possess a legal qualification to practise, are required to send in their applications, addressed to the Secretary, accompanied by copies of not more than three testimonials, given specially for the purpose, before 12 o'clock on Monday, January 31st, 1938.

The appointment is made for one year, and is non-resident.

Salary £400 per annum, with facilities for Private Pathological Practice.

The selected Candidate will be required to take up his duties not later than February 16th, 1938, preferably earlier.

All Candidates must be in attendance to appear before the Joint Committee on Wednesday, February 2nd 1938, at 4.45 p.m.

Forms of application, copy of the rules, and details of the appointment will be supplied on application to the undersigned.

HERBERT F. RUTHERFORD,
December, 1937. Secretary.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London, W.C.1.

There are vacancies for two **ANAESTHETISTS**. Candidates must be registered medical practitioners and be prepared to take up their duties at an early date.

The appointment is for one year, but is renewable and carries with it an honorarium of £15 15s per annum, and an allowance of £6 6s to provide a substitute during annual leave.

Candidates are invited to send in their applications, addressed to the Secretary, with copies of not more than three testimonials written specially for the purpose, before 12 o'clock, on Monday, January 31st, 1938, and must appear personally before the Joint Committee at their Meeting on Wednesday, February 2nd, 1938, at 4.45 p.m.

Forms of application and copies of the rules are obtainable from the undersigned.

HERBERT F. RUTHERFORD
January, 1938. Secretary

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone Road, N.W.1.

Applications are invited from registered Medical Practitioners for the following appointments:

ASSISTANT RESIDENT MEDICAL OFFICER (male). Salary £80 per annum.

RESIDENT ANAESTHETIST AND DISTRICT RESIDENT MEDICAL OFFICER, six months. Salary £90 per annum.

RESIDENT ANAESTHETIST, three months. Salary £100 per annum.

With board, residence and laundry allowance (4s. weekly). Appointments to commence on April 1st, 1938. The Assistant Resident Medical Officer is appointed for three months, and on completion will be expected to proceed to the post of Senior Resident Staff (salary £100 per annum). Obstetric experience desirable.

Applications, stating age, and with three copies of three testimonials, should be sent to the Secretary by February 19th, 1938.

H. B. STOKES,
Secretary-Superintendent.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone Road, N.W.1.

RESIDENT MEDICAL OFFICER (male or female) required for the Isolation Hospital (for Puerperal Fever) at Ravenscourt Square, Hammersmith, W.6, to commence duty on April 1st, 1938. Appointment for six months, renewable for a further period of six months. The salary is at the rate of £200 per annum, with board, residence and laundry allowance.

Applications, with copies of testimonials, should be sent to the Secretary by February 19th, 1938.

H. B. STOKES,
Secretary-Superintendent.

LONDON HOSPITAL, E.1.

Applications are invited for the post of **MEDICAL FIRST ASSISTANT AND REGISTRAR**. The appointment is for one year, but is renewable annually on application for two further periods of one year. Salary £300 per annum, payable by the Hospital and Medical College jointly.

Candidates must be fully qualified medically. Applications should arrive at the Hospital not later than by the first post on Saturday, February 12th.

ARTHUR G. ELLIOTT,
House Governor.

LONDON HOSPITAL, E.1.

There is a vacancy for the post of **FIRST ASSISTANT** to the Department of Thoracic Surgery. Candidates must be Fellows of the Royal College of Surgeons (England).

The appointment is half-time and for one year. Salary £150 per annum.

Applications should be made to the House Governor, and should arrive not later than Saturday, February 12th.

ARTHUR G. ELLIOTT,
House Governor.

LONDON HOSPITAL, E.1.

Applications are invited for the post of **SURGICAL FIRST ASSISTANT AND REGISTRAR**. Candidates must be Fellows of the Royal College of Surgeons. The appointment is for one year, but is renewable annually, on application, for two further periods of one year. Salary £300 per annum, payable by the Hospital and Medical College jointly. Applications should arrive at the Hospital not later than by the first post on Saturday, February 12th.

ARTHUR G. ELLIOTT,
House Governor.

ST. JOHN'S HOSPITAL, LEWISHAM, S.E.13.

Applications are invited for the post of **MEDICAL REGISTRAR** (male) to attend the Out-patient Department on two half-days a week, namely, Monday afternoon and Thursday morning. Honorarium fifty guineas p.a.

Applications with copies of testimonials should reach the undersigned, who will be pleased to give further information, by February 8th.

J. C. GILBERT,
Secretary-Superintendent.

ST. JOHN'S HOSPITAL, LEWISHAM, S.E.13.

Applications are invited for the resident posts of **HOUSE PHYSICIAN AND CASUALTY OFFICER** (males), tenable for six months from March 1st, 1938. Salary £100 p.a.

Applications, with copies of testimonials, should reach the undersigned by February 8th.

J. C. GILBERT,
Secretary-Superintendent.

The maximum commission payable on the sale of any Practice or Partnership in Great Britain placed exclusively in the hands of this Agency is £50 (fifty pounds), which sum covers goodwill, drugs, surgery fittings, fixtures and furniture, instruments and book debts, but not house property. Schedule of Terms will be forwarded on application.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges. No charge is made to Principals for the introduction of Locum Tenens or Assistants.

1. SOUTH-WEST COUNTY.—A ONE-SIXTH SHARE is offered in old-established Practice producing nearly £7,000 p.a. Ingoing partner must have made a special study of medicine and preferably hold the M.R.C.P. or have held a medical registration. Short preliminary assistantship. Suitable house available. Premium 2 years' purchase.
2. SOUTH-WELSH COAST.—PARTNERSHIP.—A ONE-HALF SHARE in old-established Practice producing over £3,000 p.a. Large panel. Very good house. Freehold for sale. Premium 2 years' purchase.
3. EASTERN COUNTIES.—A QUARTER SHARE (with increase later) after preliminary assistantship of about 3 months is offered in old-established Practice producing over £4,600 p.a. With substantial Panel and good appointments. Very nice house available on rental at £50 p.a. Premium 2 years' purchase.
4. MIDDLESEX.—Recently-established PRACTICE producing £700 p.a., with considerable scope. Very nice house on rental. Premium £1,250 or near offer.
5. LONDON, EAST.—Exceptionally sound chiefly working-class PRACTICE producing about £1,200 p.a., over £1,000 from Panel and appointments. Suitable house, rent £100 p.a.
6. NEAR BIRMINGHAM.—A ONE-THIRD SHARE (after preliminary assistantship) is offered in sound steadily increasing mixed-class Practice producing £3,700 p.a. Panel of nearly 5,000. Premium 2 years' purchase.
7. LONDON, SOUTH-WEST.—Middle and working-class PRACTICE. Receipts last year £705 p.a. Panel of 940. Suitable house, rent £75 p.a. Premium 2 years' purchase or near offer.
8. PARTNERSHIP.—A TWO-FIFTHS SHARE, with increase to one-half later, is offered in old-established good country Practice within about 70 miles of London. Gross cash receipts for past 12 months approximately £5,500 p.a., including large panel. Moderate expenses. Very nice house with ample accommodation and all modern conveniences. Freehold for sale or might be rented. Premium 2 years' purchase.
9. NORTH WALES.—(Welsh not essential.)—Old-established unopposed country PRACTICE in very pleasant district averaging for past 3 years approximately £2,000 p.a., of which over £600 p.a. is from panel and about £285 from appointments and clubs. Very convenient house in excellent repair, with electric light, garage, etc. Price for freehold, £1,500. Premium £3,600. Partnership introduction will be given.
10. LIVERPOOL.—Old-established PRACTICE producing about £1,500 p.a., including panel of 1,300 and appointments worth about £170 p.a. Good house in excellent position. Premium for Practice and house £3,500 (or house might be rented).
11. SURREY.—DEVELOPING TOWN.—Increasing PRACTICE producing for last year £655 and believed to offer considerable scope. Panel of about 450. Well-... with 6 bedrooms, etc., or smaller house available. Premium 2 years' purchase.
12. SOUTH-WEST.—COUNTRY TOWN.—A ONE-HALF SHARE is offered in old-established Practice producing over £1,400 p.a., but believed to be capable of considerable increase with the aid of an energetic partner. Panel of about 1,100 patients. Very good house with 2 reception, 4 bedrooms, etc., and all modern conveniences. Garden of about 1 acre. Premium for share and house, £2,500.
13. HAMPSHIRE.—NEAR COAST.—A SHARE worth about £700 p.a. with early increase is offered in rapidly expanding Practice, producing approximately £2,000 p.a. Ingoing partner must be experienced and not over 35. Suitable house can be obtained. Premium 2 years' purchase.
14. NORTHERN OUTSKIRTS OF LONDON.—PARTNERSHIP.—A NINE-TWENTIETHS share (after preliminary assistantship) is offered in well-established Practice. Receipts for last year stated to be £2,162 p.a. Panel of 1,900 patients, and appointments worth about £200 p.a. Suitable house with 2 reception, 3 bedrooms, etc. Premium £1,800.
15. NORTH LONDON.—Old-established mixed-class PRACTICE, averaging for past two years about £2,800 p.a. Panel of over 2,600. Suitable house with 2 reception, 4 bedrooms, small garden. Rent on lease £104 p.a. Premium 2 years' purchase.
16. CARLISLE.—DEATH VACANCY.—Better-class non-panel PRACTICE, producing about £700 p.a. House can be rented. Offers invited.
17. SCOTLAND.—UNIVERSITY CITY.—Old-established non-dispensing PRACTICE producing about £820 p.a., including £540 from Panel and £70 from appointments. Suitable house, 2 reception, 6 bedrooms, etc. Freehold £900, part on mortgage. Premium 1½ years' purchase or near offer.
18. LONDON.—Residential district.—Long-established good general class PRACTICE producing over £3,000 p.a., with a full panel. Good house with ample accommodation, garden and garage. Freehold for sale or might be rented. A good introduction will be given.
19. BRITISH WEST INDIES.—Better-class PRACTICE producing about £1,750 p.a. Fees 5/- to 2 guineas. Modern house with all conveniences can be purchased or rented.
20. ESSEX COAST.—Middle-class PRACTICE averaging £600 p.a. Considerable scope as receipts have declined through vendor's ill-health. Panel of about 300. Suitable house, garden and garage. Premium £1,000.
21. WITHIN 12 MILES OF CHARING CROSS.—Steadily increasing PRACTICE producing last year over £1,650. Panel of over 1,000. Easily worked. Low expenses. Compact house, garden and garage. Premium 2 years' purchase.
22. SOUTH COAST SEAPORT.—Old-established mixed-class PRACTICE producing for past year over £3,000. Panel about 1,600. Various appointments. Well situated modern house, 3 reception, 5 bedrooms. Central surgery rented at £60 p.a., part sublet. Premium 2 years' purchase.
23. RIVERSIDE TOWN.—PRACTICE has been established about 60 years. Receipts approximately £1,500 including 450 panel patients. House contains 2 reception and 5 bedrooms, etc. Leasehold for sale or might be rented. Premium 2 years' purchase or near offer.
24. SOUTH COAST.—FAVOURITE TOWN.—Old-established PRACTICE producing over £1,700 p.a. Panel of about 1,500. Appointments about £300 p.a. Scope for surgery. Prospect of hospital appointment. Low expenses. Suitable house with garden and garage on lease. Premium 2 years' purchase, to include book debts and drugs.
25. DORSET COAST.—PARTNERSHIP.—A ONE-THIRD SHARE with increase later in a well-established Practice averaging about £3,000 p.a. Panel of over 2,700 and P.M.S. about 1,000. Various appointments producing £250-300 p.a. Low expenses. Suitable house with 5 bedrooms, etc., can be purchased or rented. Premium 2 years' purchase.
26. NORTH LONDON.—Well-established middle and working-class PRACTICE producing about £600 p.a., but offering considerable scope, especially for Panel, which has only recently been started. Suitable accommodation available on rental. Reasonable offer for quick sale, vendor taking up appointment.
27. NORTH LONDON SUBURB.—Recently established PRACTICE in fast developing area. Receipts last year about £720, including Panel of about 200 patients. Architect-built modern house with ample accommodation. Freehold for sale. Premium £850 or near offer.
28. GLOS.—Sound old-established PRACTICE in beautiful country district averaging for past 4 years about £1,300 p.a. Panel over 1,100. Appointments about £80 p.a. Good house in own grounds. Freehold for sale. Premium 2 years' purchase.
29. LONDON, EAST.—Exceptionally sound old-established PRACTICE in populous area averaging for past 3 years over £2,240 p.a. Panel of approximately 3,500. Suitable house with excellent professional accommodation can be rented at £75 p.a.
30. OUTLYING NORTHERN SUBURB.—Well-established PRACTICE producing about £1,000 p.a., including panel of 525 and P.M.S. £183 p.a. Suitable house available.
31. LANC.—SEASIDE RESIDENTIAL TOWN.—Easily worked, mostly non-dispensing PRACTICE producing about £1,000 p.a., including panel of about 325. Low expenses. Suitable house available with consulting and waiting rooms, 2 reception, 3 bedrooms, maid's room, etc. Large garden. Garage. For sale or can be rented. Premium 1½ years' purchase.
32. LEEDS.—PARTNERSHIP with succession in 6 or 12 months. A 2½rd share is offered in an old-established Practice which has been held by the vendor, who is now specialising, for the past 2 years. Receipts for last year amounted to £1,176, including £492 from a Panel of about 1,150 patients. Suitable house available, freehold £900. Premium 1½ years' purchase.
33. WEST OF ENGLAND.—Good-class residential town.—A ONE-THIRD SHARE with increase up to one-half is offered in a better middle-class Practice at present averaging £1,200 p.a. Appointments worth about £350. Panel of 300 patients. Fees 5/- to 21/-. Flat available in vendor's house for single man. Rent £40 p.a., inclusive of rates.
34. NORTH WALES.—Good-class long-established PRACTICE in very attractive residential and seaside resort. Cash receipts for last 16 years over £1,200 every year. Panel 425. Good house with 2 small gardens to rent or purchase freehold. Socially very pleasant. Premium £1,800.
35. HERTS.—Country town on outskirts of London.—Very old-established PRACTICE held by vendor for 30 years. Gross cash receipts about £1,000 p.a., including Panel of 600 patients. Nice house with 2 reception 4 bedrooms, good garden on rental. Premium 2 years' purchase.
36. EAST ANGLIA.—Within reach of two good towns. Old-established unopposed country PRACTICE averaging over £1,000 p.a., including Panel producing over £450 p.a. Low expenses. Detached house with 2 sitting and 5 bedrooms, etc. Rent £70 p.a. Premium £1,750.
37. NORTH CORNWALL.—Country PRACTICE in picturesque district near coast and within easy reach of two good towns. Stated to produce nearly £1,000 p.a., including Panel of £320.
38. WITHIN 25 MILES OF LONDON.—PARTNERSHIP, with surgical scope. A one-fourth share, with increase later, is for disposal in an old-established Practice, producing about £4,800 p.a. Fees 3/6 to 21/-. A suitable house can be secured. Ingoing partner must have a Fellowship, be experienced and not over 35 years of age. A prelim. assistantship is offered.
39. COAST TOWN.—Old-established PRACTICE held by vendor for 3½ years, who now wishes to specialise. Gross receipts for last year approximately £2,183, including Panel of 770 and appointments producing about £100 p.a. Visits from 5/-. Good house available, containing 2 reception, 7 bedrooms, Professional accommodation, etc. Freehold £1,100. Premium 2 years' purchase or near offer.
40. WEST COAST.—Well-established PRACTICE, producing about £1,900 p.a., including Panel of 1,450. Suitable house on rental at £50 p.a. Premium 1½ years' purchase.
41. SURGICAL PARTNERSHIP in delightful district within easy reach of London. A fifth partner is required in an old-established Practice. There is little visiting done under 10/6, although the patients come from all classes. Ingoing partner, who must hold the English Fellowship, would do all the surgery for the firm, but must be prepared to do general practice as well. Choice of houses.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

Montreux --- Springtime

A delightful scene . . . bringing to mind, maybe, many a happy day during a well-earned rest. And talking of travel, may we suggest to practitioners when next this subject looms on the horizon, that whether they are themselves taking a holiday for pleasure, or recommending their patients to take one for health, **The World-wide Service of Cook's** is at their disposal . . . giving sound advice on all phases of travel . . . handling all these worrying details that can so easily mar the enjoyment of a holiday. Advice without obligation from any branch of

BRONCHOSPASM AND ASTHMA

A booklet surveying this subject, which includes diagrams and illustrations, has recently been published and has been sent to all members of the Medical Profession. You are invited to send for a copy should this have failed to reach you.

"THE LANCET" writes (28/4/34, p. 929):—

"We have received a pamphlet on 'Bronchospasm and Asthma,' written to bring before the medical profession the value of Felsol in the treatment of asthmatic subjects. The powders can be prescribed by the medical man in accordance with the definite regime which he decides to adopt in the treatment of a case, the claim for felsol being that its administration relieves promptly the attack of asthma by its influence over bronchial spasm, so that only the most severe cases would require the injection of morphia."

PRACTICAL PHYSIOLOGICAL CHEMISTRY

PHILIP B. HAWK, M.S., Ph.D.

By

OLAF BERGEIM, M.S., Ph.D.

President of the Food Research Laboratories Inc., New York City;

&

Associate Professor of Physiological Chemistry, University of Illinois.

With the aid of BERNARD L. OSER, Ph.D., and ARTHUR G. COLE, Ph.D.

For thirty years this volume has been a standard work, and the revised new edition now, it is felt, be as useful as its predecessors. A thorough revision has been made and much new matter incorporated.

and Alan A. Moncrieff, M.D., F.R.C.P.

FEBRUARY, 1938

With Symposium on Disorders of Digestion

This important number contains twelve articles which should be read by every doctor in active practice. The contents, which are essentially practical, include:—

ABDOMINAL PAIN AS A GUIDE TO DIAGNOSIS AND TREATMENT.

By John Morley, Ch.M., F.R.C.S.
Professor of Surgery, Manchester University; Honorary Surgeon, Manchester Royal Infirmary.

THE DIAGNOSIS AND TREATMENT OF PAIN REFERRED TO THE ABDOMEN FROM THE THORACIC ORGANS.

By Maurice Davidson, M.A., D.M., F.R.C.P.
Physician, Brompton Hospital for Diseases of the Chest.

THE SIGNIFICANCE AND TREATMENT OF INDIGESTION.

By Ernest Bulmer, M.D., F.R.C.P.
Physician, General Hospital, Birmingham.

THE SIGNIFICANCE AND TREATMENT OF VOMITING.

By Geoffrey Evans, M.D., F.R.C.P.
Physician, St. Bartholomew's Hospital, London.

THE SIGNIFICANCE AND TREATMENT OF DIARRHOEA IN ADULTS.

By S. W. Patterson, M.D., D.Sc., F.R.C.P.
Physician, Ruthin Castle.

THE SIGNIFICANCE AND TREATMENT OF OBSTINATE HICCOUGH.

By E. Bellingham-Smith, M.D., F.R.C.P.
Physician, St. George's Hospital, London.

LABORATORY METHODS IN THE DIAGNOSIS OF GASTRO-INTESTINAL DISORDERS.

By R. G. Waller, M.R.C.S., L.R.C.P.
Director of the Pathological Department, West London Hospital.

THE MANAGEMENT OF INSOMNIA.

By Henry Cohen, M.D., F.R.C.P.
Professor of Medicine, University of Liverpool; Honorary Physician, Royal Infirmary, Liverpool.

THE TESTAMENTARY COMPETENCY OF A PATIENT WITH APHASIA.

By MacDonald Critchley, M.D., F.R.C.P.
Neurologist, King's College Hospital; Physician to Out-patients, the National Hospital, Queen Square, London.

VARIETIES OF CARDIAC DYSPNOEA.

By R. O. Moon, D.M., F.R.C.P.
Consulting Physician, Royal Waterloo Hospital, and the Hospital for Diseases of the Heart.

DIET IN HEALTH AND DISEASE: VIII.—DIET IN KIDNEY DISEASE.

By Robert Platt, M.D., F.R.C.P.
Physician, the Royal Infirmary, Sheffield.

NOTES AND QUERIES:—

The Treatment of Large-Spore Animal Ringworm.
Impotence.
Sulphanilamide and Meningitis.
Disseminated Sclerosis.

PRACTICAL NOTES:—

Cure of Undulant Fever with Sulphanilamide.
A New Tuberculin Patch Test.
Calcium as an Antacid.
Suction Lavage of the Nose.
Calcium by Buccal Route: A Simple Method.
The Treatment of Psoriasis with Massive Doses of Crystalline Vitamin D.
The Treatment of Sun-Burn.

Surgical Diseases of the Mouth and Jaws—by Earl C. Padgett, M.D.

Surgical Diseases of the Mouth and Jaws. By Earl Calvin Padgett, B.S., M.D., F.A.C.S., Associate Professor of Clinical Surgery, University of Kansas School of Medicine; Associate Professor of Oral Surgery, Kansas City Western Dental College. Octavo of 807 pages, with 331 illustrations. Cloth, 45s. net.

A New Book for the Surgeon, Medical Practitioner and Dentist

Dr. Padgett's new book is a comprehensive, up-to-the-minute discussion of how to manage and treat the Surgical Diseases of the Mouth and Jaws. It is one of the most important works on this subject for many years. Dr. Padgett emphasizes those disorders met most commonly in general practice. There is an unusually fine chapter of 40 pages on the technique of Plastic Surgery and numerous other features throughout the book such as clinical discussions, things to avoid, post-operative pneumonia, care of the heart, etc. Treatment is described and illustrated step-by-step and both surgical and non-surgical methods are given in full detail.

Extirpation of the parotid gland. The external carotid has been ligated, the parotid gland is isolated, the posterior half of the ramus of the mandible has to be removed so the whole of the parotid gland can be removed en bloc because part of it is beneath the mandible. The ramus may be cut across with a circular saw or a Gigli saw.

PARTIAL CONTENTS of this FINE NEW BOOK

Study and Diagnosis
Anatomic Considerations
Asepsis and Materials of Surgery
Wounds of Soft Tissues
Complications of Wound
Injuries of Bony Framework
Injuries of Teeth and Alveolar Processes
Fractures of Jaws
Fixation Methods for Fractures
Dislocation of Lower Jaw
Inflammations and Diseases of Soft Structures
Removal of Teeth and Related Matters
Inflammations and Diseases of Face and Lips
Inflammations and Diseases of Buccal and Pharyngeal Cavities
Inflammations of Antrum

Inflammations and Diseases involving Neck
Inflammations and Diseases of Jaw Bones
Inflammations and Diseases of Temporomandibular Joint
Inflammations and Diseases of Salivary and Lachrymal Glands
Neuralgias and Motor Derangements
Malrelations of Teeth and Jaw Bones
Facial Clefts
Treatment of Bone Cleft and Neighbouring Soft Tissue
Repair of Cleft Lip
Cleft Palate Surgery
Repair of Palate Proper
Other Anomalies, Sinuses, Cysts, and Benign Tumours of Congenital Origin

Benign Tumours of Soft Tissues
Malignant Neoplasms of Soft Tissues
Irradiation in Treatment of Malignant Neoplasms
Operations for Malignant Neoplasms of Soft Tissues
Management of Lymphatic Areas
Tributary to Epidermoid Carcinoma
Selection of Therapy and Prognosis for Malignant Neoplasms of Soft Tissue
Maxillary Tumours of General Origin
Other Benign and Malignant Tumours
Primary in Bones of Face and Jaw
Resections of Jaw Bone
Surgical and Prosthetic Restoration
Anaesthesia

DEAF AIDS

Their Effect Upon Speech

In a recent report of research work carried out under the auspices of the Medical Research Council it was written—"Any distortion introduced by unsuitable hearing aid apparatus is usually reflected in the speech of the user." The broken line curve in the illustration shows the enormous distortion present in the ordinary micro-telephone or bone conduction type of hearing aid. Such distortion often produces a change of voice to a harsh unnatural pitch and means continual strain to the user. The continuous line curve shows the amplification of an AMPLIVOX High Fidelity Aid, giving amplification over a wide frequency range, but alterable at will to suit the nature of the deafness. With such a hearing aid the reproduction is of such high quality as to re-educate the hearing and to bring about an improvement in speech where this has deteriorated. This is quite apart from the excellent results which are given by the AMPLIVOX, the first and most widely used High Fidelity hearing aid. We should be glad to send you full particulars of the AMPLIVOX hearing aids.

ALASIL

Safe Salicylate Therapy

THE popularity of acetyl-salicylic acid is undoubtedly due to the fact that it is one of the safest and most effective non-narcotic analgesics available. Too often, however, its use has been discarded by the physician on account of its tendency to irritate the stomach and because entirely pure preparations are not always available.

"Alasil" provides the beneficial therapeutic effects of pure acetyl-salicylic acid in such a form that it is acceptable even by disordered digestions. This tolerability is due to the fact that it combines calcium acetyl-salicylate—the least irritating salicylate compound—with "Alocol," a potent gastric sedative and antacid.

Since "Alasil" is better tolerated than acetyl-salicylic acid its use can be pushed or prolonged to a much greater extent than the latter. "Alasil" is, therefore, an analgesic, antipyretic, and anti-rheumatic which can be employed with complete confidence in all the many conditions in which such an agent is indicated.

A supply for clinical trial, with full descriptive literature, sent free on request.

NETTLERASH • TETANY • MIGRAINE • DELAYED
UNION OF FRACTURES • BACKWARD DENTITION IN
CHILDREN • MUSCULAR CRAMPS... AND IN PREGNANCY

OSTOCALCIUM Tablets

IMPROVED FORMULA NOW GENERALLY AVAILABLE

The Ostocalcium Tablets now being issued possess improved flavour, friability and keeping properties. Also the calcium content has been substantially increased. The new tablets incorporate $2\frac{1}{2}$ grains of calcium phosphate, in addition to $7\frac{1}{2}$ grains of calcium sodium lactate and 500 international units of vitamin D. Thus each tablet now provides a total of $1\frac{1}{2}$ grains (0.1 gram) of assimilable calcium, or twice as much as the tablets of the old formula. There is, however, no change in price.

★ **OSTOCALCIUM TABLETS**
Prices (except in Eire): Tins of 50, 2/3;

Prevent the Cold and the attack of Influenza

The National Fitness Campaign is emphasising, among other things, the fact that adequate nutrition is essential for health. And there is ample proof to show that those who habitually take enough of the right kind of food are able to resist infection better than those whose diets are less well chosen.

It is well known that the modern diet tends to supply comparatively little of the B vitamins and that these factors play a special role in helping to prevent illness.

Marmite is prescribed extensively for it contains all the vitamins of the B group and has proved of particular value in combating winter illnesses.

Marmite served as a hot drink provides a popular means of fortifying the system. It helps to prevent illness, is beneficial to the patient, and is especially indicated during convalescence.

The **MARMITE** FOOD EXTRACT CO. LTD.,
35 Seething Lane, LONDON, E.C.3.

In jars: 1-oz. 6d., 2-oz. 10d., 4-oz. 1s. 6d., 8-oz. 2s. 6d., 16-oz. 4s. 6d. Special quotations for Marmite packed for use in hospitals, clinics, welfare centres, etc.

SCHOOL CHILDREN ESPECIALLY . . . ARE FOND OF THIS PURE FRUIT JUICE

GOOD work, as every doctor knows, is very often dependent upon good health. And a well-regulated diet is important for maintaining good health.

Dole Hawaiian Pineapple Juice is the natural juice of sun-ripened, Dole-grown pineapples. It contains no added sugar or preservatives of any kind.

The exclusive Dole Fast-Seal Vacuum-Packing Process retains, to a high degree, those important fresh-fruit constituents found in the ripened pineapple so valuable, not only to growing children, but to adults as well! Also, this tangy, tropical juice is a natural source of vitamins A, B, and C. That's why, with schooltime, when parents are asking about diets and menus for their children, you can recommend with assurance pure, unsweetened Dole Pineapple Juice—the original pineapple juice from Hawaii.

J. K. Husband & Co., Ltd., 10 Eastcheap, London, E.C.3.

HERE IS A TYPICAL ANALYSIS OF DOLE PINEAPPLE JUICE:

Moisture	85.3%	Crude Fibre	0.02%
Ash	0.4	Titrate acidity as citric acid	0.9
Fat (ether extract)	0.3	Reducing sugars as invert sugar	12.4
Protein (N x 6.25)	0.3	Carbohydrates other than sugars (by difference)	0.38

P.S. We would like you to enjoy a long cool glass of this refreshing juice! Write to us on your letterhead and we will send you a sample tin free.

THE LEI WOMAN—An old Hawaiian custom ever new is the habit of decorating departing or returning friends with beautiful wreaths of native flowers. The fragrant ilima, maile, plumeria, pikake and ginger are used extensively in the making of leis. It is a picturesque sight on steamer docks to see the native women with their skilful hands weaving the fragrant garlands.

OVALTINE

IN SICKNESS AND CONVALESCENCE

GODDESS NEITH.
Personification of waters Abydos which was endowed with self-creation.

THE impairment of digestive powers which is commonly met with in the feverish patient, combined with the lack of desire for food, often aggravates the difficulty of adequately replacing the increased loss of energy and destruction of tissue which occur.

"Ovaltine" provides a satisfactory solution to the problem of alimentation in many cases of sickness and in the stage of convalescence after severe, prolonged and debilitating illnesses, where an easily assimilable, palatable and concentrated nutrient is required. It is always acceptable.

"Ovaltine" replaces with advantage the ordinary milk preparations which so often prove distasteful to the invalid. Prepared from full-cream milk, eggs and malt extract in carefully balanced proportions, it provides complete nourishment in the most readily assimilable form.

A liberal supply for clinical trial sent free on request.

A. WANDER, LTD., 184, Queen's Gate, S.W.7. Works: King's Langley, Herts.

Parenteral Liver Extract with Vitamin B₁.

A new highly concentrated and refined solution of Liver Extract for the treatment of pernicious anaemia.

Dosage: For treatment of cases in relapse, at the time treatment is instituted, a dose of 0.5 c.c., given on three successive days, is usually indicated. After the initial injections on three successive days, a dose of 0.5 c.c. at intervals of one to two weeks usually suffices to maintain an adequate red cell response.

Supplied in packages containing three 0.5 c.c. rubber stoppered ampoules, and in 5 c.c. rubber stoppered ampoules.

INSULIN 'A.B.'

Insulin A.B. was the first British insulin offered commercially to the medical profession. Its manufacture on an industrial scale was the direct result of research carried out by the joint manufacturers in their physiological and chemical laboratories; its supremacy has been fully maintained by the persistent work of the research staff engaged in its production. Insulin A.B. has a world-wide reputation for its strictly safeguarded sterility, its carefully standardised strength, its freedom from toxic reactions, and its stability in hot climates.

Supplied in three strengths:

20 units	per c.c.	Packed in bottles containing:	
		5 c.c. (100 units)	1/6 each
		10 c.c. (200 "	2/10 "
		25 c.c. (500 "	6/10 "
40 units	per c.c.	Packed in bottles containing:	
		5 c.c. (200 units)	2/10 each
80 units	per c.c.	Packed in bottles containing:	
		5 c.c. (400 units)	5/6 each

Prepared for the mouth and throat

'Dettolin' is specially made to kill quickly the micro-organisms concerned in affections of the mouth and throat. It contains, among other ingredients, the active germicidal principle of 'Dettol'—the modern antiseptic. For all its high germicidal efficiency, 'Dettolin' is soothing and gentle on delicate tissue. It has the added advantage of being distinctly pleasant to use, an important factor when frequent and regular gargling is prescribed.

'Dettolin' is obtainable from Chemists and Medical Suppliers.
Price 9d. and 1/3. Sample, and full information on request.

WHOOPING COUGH

Detoxicated Whooping Cough Vaccine (Genatosan) has proved remarkably successful. Reports received from medical practitioners state that it usually reduces the frequency of the paroxysms after the first injection, and subsequent injections almost invariably clear up the condition. Owing to the elimination of the toxic elements of the germ during the process of manufacture, this vaccine may be given to infants and young children, in doses sufficiently large to produce the desired therapeutic effect, with an absence of harmful reaction.

The following is typical of many reports received from physicians:—

"I have been making a somewhat extensive use of your Detoxicated Vaccine for Whooping Cough, and am pleased to say that the results have been almost invariably gratifying. In nearly all my cases the very distressing symptoms have disappeared after the third injection." M.D.

Additional information regarding this Vaccine will gladly be supplied on request.

‘PLASTULES’ FOR ANÆMIA

Small dosage, easy assimilation, and excellent results are all characteristics of ‘Plastules’ brand Hæmatinic Compound. The suggested daily dose of only three ‘Plastules’ Plain is usually sufficient to induce an early response in cases of secondary anæmia. ‘Plastules’ obviate the

necessity of massive iron feedings, ensure the co-operation of the patient and provide an economical form of iron medication. . . .

Doctors are invited to write for samples and literature on ‘Plastules’ Brand Hæmatinic Compound Plain and ‘Plastules’ with Liver Extract.

Formula

Intestinal glands	- - 0.05	grms.
Biliary extract	- - 0.10	"
Lactic ferments	- - 0.05	"
Agar-agar	- - - 0.05	"
Fiat tablet	- - - 0.35	"

Initial Daily Dose
Two Tablets

Laxatives, it is well known nowadays, must have two essential characteristics.

1. They must be biological, i.e., they must accord with and imitate in their action the natural physiological processes of the intestine.
2. They must be capable of educating the intestine, so that the habit of a laxative is not formed and the intestine can function unaided when bowel adjustment is attained.

Taxol has both these advantages.

Taxol has not the violent irritant action of many laxatives and purgatives, but stimulates the intestine by processes which resemble those of nature. The intestinal gland which is an important part of its composition acts on the intestine by reinforcing the deficient function which has culminated in constipation. This stimulating action is gentle, and does not force the weakened intestine to efforts beyond its power, which would culminate in aggravation of the constipation.

Taxol is not habit-forming. It re-educates the intestine to resumption of normal function unaided, thanks to the biological nature of its action. It contains no irritant drug of violent and artificial action to which the intestine can become accustomed. On the contrary, many stubborn cases of constipation, after a course of TAXOL, revert to normal and regular peristalsis.

15, MARK LANE, LONDON, E.C.3

Convalescence

In convalescence a tonic is required that will co-operate with, and augment, the natural recuperative powers of the body, rather than one which will have only an immediate stimulating effect. In the latter case there is always the danger of disappointment, due to an artificial improvement that the natural powers are unable to stabilise.

Medical evidence extending over many years has established the value of Sanatogen in promoting convalescence. In "The Elements of Pharmacy, Materia Medica and Therapeutics", Sir William Whitla writes:—

"... The interesting and valuable researches conducted by Tunncliffe and Beddoes upon metabolism, in which Sanatogen was experimented with, establish the fact that its organic phosphorus is almost entirely assimilated when the food is administered in the amount necessary for the needs of the body. When given in addition to other food, the amount of nitrogen and phosphorus retained in the organism is increased; the tissue metabolism is more complete, the constituents of the ordinary food being more thoroughly utilised; appetite is increased and the body weight augmented."

Similarly gratifying observations are constantly being notified, and, as Sanatogen is entirely free from fats, sugars and carbohydrates, it can safely be prescribed in all types of cases. It is rapidly and easily digested and assimilated, even in cases exhibiting severe gastric inflammation, and for this reason it is a valuable addition to enemata. It can be added to any non-acid beverage or food, and, consequently, monotony in its administration can always be avoided.

Laxatives for Children

The choice of laxatives for children is governed by many exacting considerations. To aid the Physician in assessing the merits of Andrews Liver Salt, its main characteristics are briefly listed below:

- 1 The dosage is easily adjusted according to age.
- 2 It is pleasant-tasting. Children accept it readily.
- 3 The taking of Andrews is not followed by the griping or other pains that often lead to psychological revulsion against the more drastic purgatives. Its laxative action is extremely mild and is due to the presence of magnesium sulphate and other salts, which increase the fluid content of the bowel by Osmotic action and so lead to painless, easy evacuation.
- 4 Andrews has a soothing effect on the stomach and a physical cleansing action on the stomach walls which breaks up any unhealthy coating of mucous. It is also useful as a gastric sedative in the bilious attacks to which many children are prone.
- 5 The action of Andrews is not limited to the elimination of waste; it also corrects excess acidity, stimulates the flow of bile and generally aids the digestive system.
- 6 Andrews creates no dependence on artificial aid, but can be discontinued when the need for it ceases.

DOSAGE FOR CHILDREN:

From two years of age, it is safe to start with $\frac{1}{2}$ teaspoonful and to increase the dose as necessary for older children.

ANDREWS

LIVER SALT

An 8-ounce Tin will be sent free, on request, to any Member of the Medical Profession.

A NEW OUTLOOK ON THE PHYSIOLOGY AND PATHOLOGY OF MENTAL AND EMOTIONAL STATES*

BY

F. A. PICKWORTH, M.B., B.S., B.Sc.

Director, Joint Board of Research for Mental Disease, City and University of Birmingham

(WITH SPECIAL PLATE)

The Present Impasse in Mental Disorder Research

The central nervous system contains a large number of neurones each with cell body, dendrites, axon, collaterals, and synapses, connecting with one another in a manner similar to the communication lines of a number of automatic telephone exchanges; the physiology of the relation of this complicated system of neurones to mental function, emotional reaction, and conduct is, however, obscure. Eminent scientific men have spent their lives in this research, but their work has merely added to our already vast store of knowledge without solving the main problem. At the recent Royal Society of Medicine discussion of the relation of endocrines to mental disorder no agreement was come to regarding this, and for various reasons the discussion was not published; at the psychiatric section Dr. E. Goodall in his presidential address lamented the fact that in spite of enthusiastic work over the last half-century little real progress in either aetiology or treatment had been made. He said: "We have in my opinion made no advance in our knowledge of the pathogenesis of the psychoses." In America, Freeman (1937), after ten years' intensive research in psychiatry, says: "Little more is to be gained from the study of the anthropologic, nosologic, or pathologo-anatomic features of the body in persons suffering from mental disorders." Hoskins (1937), with reference to schizophrenia, states that "the morphologic pathologist has sought in vain for a basis of the disorder." Fulton says that although physiological functions have a cerebral localization few would venture to localize the higher intellectual functions: Lashley says, "I am coming to doubt the validity of the reflex arc hypothesis even as applied to spinal reflexes"; and Professor Golla in his 1937 Maudsley lecture said the physiological make-up of personality does not admit of description in purely scientific terms.

The biogenetic deteriorated-neurone theory of germ-plasm defect, with possibly a few rare exceptions, can no longer be upheld, since the evidence upon which hereditary theories have been based—apart from the conditioning of environment—has been shaken by Paterson, Penrose, and Findlay. The success of various shock treatments (malaria, hyperpyrexia, and insulin)—although this therapy is possibly on the right lines—is without approved explanation. The toxin-impaired-neurone theory, which we have

cherished so long and expended so much energy upon, is untenable for reasons which I shall give later; and the work of Pavlov's school on conditioned reflexes involves almost incredible precautions in the isolation of animals during experiment, in order to eliminate the hypothetical investigatory reflex—precautions totally out of proportion to what we know from our own observations and experience are necessary to establish conditioned reflexes in ourselves or animals, suggesting that the theoretical basis upon which they are working is incomplete. Sherrington (1933) says: "We have to regard the relation of mind to brain as still not merely unsolved but still devoid of a basis for its very beginning." The question naturally arises whether the physiological conception of mental and emotional states upon which research is based is lacking in some fundamental quality. Superstition demands an infinitely more complex control of the already complex nervous system, and thus hinders study of a humbler control by the vascular system.

Higher Reflex Action in Relation to Mental and Emotional States

Neurones transfer energy by electrical impulses† which cease at the next receptor organ or dendrite after having there effected an electro-chemical ionic change (liberation of potassium ions). In the higher animals this change results in a synthesis of a transmitter substance which, if quantitatively sufficient, effects a motor response or a discharge of the neurone with which it is in contact, the new electrical impulse thus set up having different characteristics from the original impulse. A sensory impulse is thus transmitted by alternate physical and chemical agencies, the latter (but not the former) often reinforced by other impulses, till eventually an end-organ is excited (motor response), or it becomes lost by reason of quantitative insufficiency of some synapse in its path. Stimuli reaching the central nervous system and the nerve potentials there built up are annihilated within a fraction of a second; even the central excitatory and central inhibitory states (Sherrington school) attain their maxima in 0.006 and 0.05 second respectively (traces only remaining as long as 0.015 and 0.2 second respectively); all such are instantaneous in comparison with the time duration of mental and emotional states (hereinafter referred to as m.e.s.). The brain itself is incapable of

* An amended lecture read to the Midland Mental and Pathological Society, October, 1937.

† Chemical diffusion along an elephant's motor nerve would take geological time to effect a response.

THE IMPORTANCE OF PRECISION POLISHING

In order to obtain uniformity of calibre and complete roundness of strand along its entire length, A. & H. Catgut is polished by automatic machinery.

Hand polishing of individual strands fails to obtain this desirable precision and uniformity in the production of surgical catgut strands.

One of the modern advantages incorporated in the production of A. & H. Catgut.

Integrity of the Central Nervous System in Mental Disorder

In psychiatry none of the present theories of disordered mental states attempts to account satisfactorily for the clinical remissions and resuscitations which are universally recognized. A patient on admission to a mental hospital may temporarily so improve that certification is very hard during the first two or three days. Dr. D. McRae has remarked that mental hospitals would be extremely difficult to manage were it not for the fact that the majority of the patients are comparatively lucid for most of the day. Temporary mental improvement follows any new treatment, a fact which has given bias not only to individualistic conceptions of aetiology but also to the patient and his relatives in the use of patent medicines and palliative home treatments that are quite devoid of real therapeutic value. Dr. A. M. McCutcheon has told me that a patient in his care maintained a mute vegetative existence for sixteen years, during which he "couldn't have been more like a cabbage"; he then had a fatal attack of pneumonia, coincident with which his mental clarity returned and he asked for his friends, with whom he conversed in a perfectly rational and lucid manner. In 1929 Loevenhart discovered that by asphyxiating mute and apathetic cases of mental disorder almost to the point of death there followed a period during recovery when they became perfectly rational and apparently mentally normal: unfortunately, as the state of cerebral stimulation passed off the identical mute apathetic state always recurred. Other methods of cerebral stimulation are known, such as heavy poisoning with sodium amytal, and recently Hallay invented a method of so-called brain massage by which restoration of sanity in a mentally disordered case was possible by alternate rhythmical compression of the jugular veins. Even certain states formerly considered neurological (torticollis and Parkinsonism) are similarly temporarily relieved by such methods of cerebral stimulation, but they always recur to the identical original condition as the stimulation ceases.

The lucidity, which occurs naturally, or after shock treatments (primitive, surgical, protein, insulin, and others), after prolonged narcosis, and during infections or artificial cerebral stimulation, establishes the significant fact that the synaptic connexions of the central nervous system in the mentally disordered states may, in contrast to the permanent dementia that is due to destructive lesions of nerve parenchyma, remain for many years inert but intact and capable of functioning on the normal personality pattern. This anatomical integrity of the central nervous system is illustrated in its simplest form in stammering—where the nerve reflex pattern of speech is obviously intact, but where direct function is in some way inhibited, as by spasm and ischaemia of the cortex; and in the restoration of lost function seen with excitement in cases following epidemic encephalitis. A story relates how an ancient relative rushed into the road and saved a child from a runaway horse-and-cart; for years before and for ever afterwards he was quite unable to walk!

Neurological conditions are occasionally seen in mental hospital cases, but not to the extent generally supposed, and it is believed that application of the differential diagnostic test of cerebral stimulation would show that some of these conditions are not really neurological, in the sense of nerve pathology, but psychiatric (meaning a disorder of the mediator of alternate synaptic functions

—that is, the m.e.s.). When loss of nerve elements occurs the reflexes dependent upon such elements are lost for ever—and gross atrophy of the cortex has long been associated (quantitatively, according to Lashley) with dementia; nevertheless the occurrence of lucidity from natural or artificial means, even if only temporary, firmly establishes the integrity of that part of the central nervous system subserving the recoverable function in mentally disordered and neurological cases, including clinical dementia without gross brain atrophy.

Synaptic Patterns and their Control

Many speculations have in the past been advanced of the identity of m.e.s. with synaptic function. McDougall (1901) says the physical basis of memory is of the nature of a dielectric stimulation at the synapses; in other publications he introduces speculations of synapses as the seat of psychological processes, consciousness being a fusion of many such activities. Pavlov considered the mind as a mosaic of inhibitions and facilitations of synapses, but emphasized its dynamic character. Others have attempted to correlate mental disorder with the pathology of the cerebral vascular system: among these the work of Spielmeyer will always be remembered, even although his later opinion was that the areas of functional ischaemia and necrosis described by him could not usefully be correlated with a fundamental relation to mental disorder. To these workers the extreme vulnerability of the ganglion cells to oxygen lack has been a stumbling-block causing them to abandon some useful preliminary work. For example, a significant experiment was published by my predecessor, the late Sir Frederick W. Mott (1907), who applied a stimulus to the leg cortical area of the brain, at the same time firmly pressing upon the upper cord sufficiently to indent it, and noting that motor impulses were not affected by such pressure: he then applied light pressure upon the lumbar cord, just enough to cause ischaemia of the cellular (actually of the synaptic) area, upon which impulses promptly ceased, even considerable increase of the strength of the stimulus failing to effect any response of the leg muscles.

The transmission of impulse within a neurone follows an "all or none" law: its physical character admits no modification, and it does not suffer decrement, as was formerly supposed, when a portion of nerve fibre is narcotized. Decrement occurs at, and only at, the synapse where the original nerve impulse ceases and chemical transmission takes its place. The dendrites of a neurone have many synaptic connexions, and are influenced by numerous inhibitory states and excitatory stimuli, which, if in an exact time-identical phase, would leave an effective or insufficient physio-chemical resultant. Infinitesimal time differences in the reception of such stimuli, however, are important, since at any instant the resultant may excite the neurone, then briefly but quite refractory to other stimuli, which are then lost. Sherrington (1933) says that "if nerve activity has relation to mind one can hardly escape the inference that nerve inhibition must be a large factor in the working of the mind." Synaptic function can be inhibited by reduction of its blood supply, any such inhibitory delay preventing premature discharge of the neurone and allowing summation of more stimuli, with greatly enhanced value of the motor response. Reflexes which previous experience has shown to be advantageous can be facilitated by increased blood supply to the synapses, and disadvantageous responses inhibited by relative ischaemia of the respective synapses, this control being part of the capillary mosaic and therefore part of the m.e.s. existing at the time.

originating nerve excitation, and the widespread faulty appreciation of this fact in relation to the anatomical "centres" of physiological function in the brain has resulted in the appearance in the literature of erroneous statements of hormones "stimulating" brain centres.

Mental states, although physiologically associated with the central nervous system, possess a somewhat different function and characteristics; attempts to identify them have been and always must be failures. Sherrington (1933) says that "the history of the brain seems to suggest mind as at the outset a sort of adjunct to the nerve management of motor behaviour." Parker (1932) says the dawn of intelligence is seen in the capability of a primitive animal to refuse food when engorged. The word "mind" is best limited to such differential control of alternate nerve pathways (see Fig. B) influencing behaviour, and includes also subconscious function. The distinction between subconscious and conscious varies in the one direction with evolution, growth, and age; and in the other with learning, training, or physiological defect, although limited in the latter respect. The conscious attempt of the child in its first walk contrasts with the adult's conscious attempt at directing any part of the walking phenomena—which decreases rather than increases efficiency; and the brilliance of an artistic performance may be enhanced by a slight general mental inhibition (alcohol). Skilled movements, such as those of pianists and typists, are due to a finely detailed control of synapses; a really expert skilled worker can read, talk, and otherwise pay little conscious attention to his work whilst at the same time doing it quite efficiently.

Mental function is usually somewhat vaguely identified with dynamic activities incident to the characteristics of nerve impulse which have been established by the study of isolated muscle-nerve preparations, together with the principles of functional integration of neurones, conditioned reflexes, and supposed, but impossible, long delay paths in the central nervous system. A single nerve impulse is exceptional rather than the rule, what is generally regarded as an impulse being shown by electrical methods to be built up of a large number of successive impulses. The central reflex time is practically instantaneous, being in some instances less than half the total reflex time; motor effects of longer duration can only be due to repetition of the original or other stimulus. The time relations of higher reflex action of the central nervous system, assuming the stimulus is not continued or repeated, therefore cannot be conciliated with those of m.e.s. (which take time to develop and persist several minutes, remaining as traces hours, days, or even years afterwards); thus the latter must have a different physiological basis. Apparently no one has previously attached any importance to the fact that m.e.s. are static rather than dynamic phenomena, and that they are potentially independent of the higher reflexes of the central nervous system whose metabolism they control.

Conduct in Relation to Mental and Emotional States

Since motor behaviour (which is the dynamic end-result of higher reflex action) is constantly changing, even in the same individual, a consideration of the controlling influences of m.e.s. upon conduct is necessary. Certain facts are readily ascertainable from our own experiences; for example, the same stimulus may result in different motor effects under different circumstances—that is, with differing m.e.s. The reaction and behaviour to a plate of hot soup at the beginning or end of a heavy dinner typify the most primitive example of the same stimulus

resulting in a behaviour determined by the then existing mental and emotional state; the word "cats" to a dog nearly asleep may evoke partial opening of one eye, but if the dog is alert and there is a near-by rustling, immediate action ensues, involving the whole musculature of the animal. Conversely, widely different stimuli may produce similar motor responses: recognition—which is a mental state—can be observed in a dog receiving an olfactory, auditory, or visual stimulus from its master. Stimuli received during any particular m.e.s. have their characteristic limitation of motor response (conduct)—a fact exploited in political gatherings, and shown by the example that a well-meaning harmless intervener in a quarrel may get his nose broken; docile animals when frightened, or in other unaccustomed m.e.s., may scratch, bite, or otherwise harm their keepers.

Many stimuli received during a certain m.e.s. are lost or inhibited by training; all others automatically (robot-like) result in responses (conduct) in conformity with the particular mental and emotional state. A quiet demeanour in a sick-room is essential because the patient is consciously or unconsciously preoccupied with painful stimuli (an increased activity of those synapses which we know subserve the reflex paths of pain being necessarily paralleled by increased local capillary function), and therefore any uncompensated stimulus intensifies shock—the m.e.s. equivalent to subconscious pain. Unexpected loud sounds or strong stimuli cannot readily be compensated, and elaborate precautions are sometimes taken to prevent street noises reaching the sick-room. When an "irritable" mood prevails, the wireless, clock-tick, canary, door-bell, telephone, and animals' and children's noises are stimuli which may and do excite impulsive behaviour, whereas with a good mood such sounds are stimuli to appropriate motor responses.

Emotional states (anger, friendliness, hostility, approval) are clinically recognized by the facial appearance or attitude. A mother's estimation of her child's capabilities is often emotional rather than intellectual; but such distinctions are of little import, since both mental and emotional states are dependent upon the same mechanism (the only real difference being the fewer possible number of capillary patterns in the brain stem (emotional) as compared with those of the cortex (intellectual)). Mental states are best visualized by reference to commonplace expressions such as "remembering," "change of frame of mind," "conversion," "discipline," "bias," "opinion," and "temporarily insane." States alternating between normality and senility are illustrated by aged acquaintances; in whom when undisturbed there is lack of expression, with lustreless eyes and slow movements; but on mention of a favourite topic the eyes sparkle, the features show emotion, the facial furrows disappear, and an associated mental acuity develops which reverts to the original state on changing to another topic of little interest.

Conduct in relation to specific stimuli is therefore not due, as often supposed, to a more or less permanent integrated nervous path through the central nervous system, nor is it even due to a large mass-inhibition of unwanted motor responses; it is due rather to a capricious control of all the related delicately balanced synaptic paths by a mediator, known clinically as m.e.s., which enables each and every muscle of the body to take its share in the general attainment of some effect—as seen in cinematograph pictures and photographs of professional athletes and sportsmen. Fig. A shows diagrammatically how this happens when the mediator inhibits or facilitates synapses collected in groups.

control of the arterioles as Woollard has shown for the somatic capillaries. The carotid sinus merely determines the pressure distribution between the head and the rest of the body, electrical stimulation dilating the cerebral vessels: the importance of gross interference of function from contiguous sepsis in relation to disturbed mental states should not be minimized until first subjected to histological proofs. Section of the cervical sympathetic increases the number of patent brain capillaries, and mental improvement has followed some of these operations in selected cases (Royle, 1932).

Danders (quoted by Forbes, 1928) in 1850 obstructed the nose and mouth of animals for ten seconds and observed a dilatation of cerebral vessels through an air-tight window in the skull, using a magnification of $\times 45$. Constriction* of cerebral vessels occurs when the carbon dioxide is low, when the oxygen is high, when the blood becomes hypertonic, when the cervical sympathetic is stimulated, when the fear area in the hypothalamus is stimulated (Stavraky, 1936), and with adrenaline after sympathectomy or ergotamine. Dilatation occurs with increased carbon dioxide, trauma, acidosis, stimulation of the seventh nerve, fall in blood pressure, gaseous embolism, acetylcholine, histamine, adenylic acid, nitrites, and a number of other local elective substances, including, for example, that of pituitary secretion on the parietal region. Stimulation of the tuber or pressure with a small sponge, or stimulation of the ventral and medial parts of the thalamus, also dilates pial vessels. Himwich (1937) finds that, in contrast to other viscera, the arterial quality of the venous return from the brain in dogs increases parallel with hypoglycaemia, giving a biochemical explanation; another explanation is also possible, since this phenomenon under other conditions is accepted as proof of cerebral capillary dilatation. Experimental pharmacology shows the selectivity of capillary reaction to drugs. Both histamine and CO_2 contract the capillaries of the lungs but dilate those of the brain; urethane dilates capillaries but not arterioles. Strychnine has formerly been supposed to act directly upon the synapses, but Olkon (1930) observed by direct microscopical examination the contortions, kinking, and spasms resulting in brain capillaries from injection of strychnine into animals, a finding which, taken in relation to clinical symptoms, makes a significant contribution to the new outlook I have put forward in this paper.

A fall or rise in blood pressure is accompanied by distinct modification of feeling and thinking (Gordon, 1930). Mental effort causes an increase in the oxygen and decrease in the carbon dioxide of the jugular blood; that is, a general dilatation of cerebral capillaries (Lennox, 1931). The rapidity with which a "change of mind" or emotion can follow sensory stimuli shows that impulses of the central nervous system are of primary importance in adjusting the mosaic of capillary pattern to altered circumstances and behaviour requirements. Once "set" a capillary pattern tends to persist and even to re-form after diversions or sleep.

The controlling influence of the mosaic pattern of capillary activity upon the pattern of facilitation or inhibition of groups of synapses receives support from recent work on the relation of acetylcholine to synaptic function. A nerve impulse releases potassium ions at the synapse, which in cholinergic fibres effects a synthesis of acetylcholine and excites the second neurone. When

an excitator effect is thus transmitted through a synapse by acetylcholine the latter leaks out around the muscle or nerve: potassium ions similarly leak away during passage of a nerve impulse, and both these substances cause severe depression of further responses to subsequent nerve stimuli. The capillary circulation immediately and completely removes any free acetylcholine that is not limited to the synaptic membrane, also restoring altered salt concentrations: such action may be also said to effect a control of synaptic metabolism and function. Repeated stimuli of the cervical sympathetic cause a continuous output of acetylcholine from the sympathetic ganglia, which, however, soon decreases in amount (recognizable clinically by diminution of motor effects and chemically by the lesser amount of acetylcholine in the perfusate), but suddenly increases, as shown both by motor response and by its quantitative increase in amount in the perfusate, when a small quantity of blood plasma or serum is allowed to reach the synapse again. The vascular supply is therefore normally of primary importance in maintaining the local synthesis of transmitter substance (acetylcholine) and in removing such acetylcholine as has leaked away from the synapses into the surrounding tissue, where its effects are distinctly undesirable. The relatively enormous amounts of oxygen consumed at the synapses (amounting to one-tenth of the total body consumption of oxygen) also indicates the dependence of synaptic function upon the blood supply (for further correlations see Pickworth, 1937).

Neurones and the Action of Toxins

The inhibition of function which often characterizes cases of mental disorder, together with the well-known fact that brain tissue absorbs with avidity many kinds of toxins mixed with it *in vitro*, has directed many, including myself, to the attractive theory of direct action of toxins upon the ganglion cells of the brain: and some regions of the brain have been held to be specially vulnerable to the action of toxins (Vogt's pathoclisis).

Intestinal toxæmia has for a long time been associated with mental disorder, and especially with the katatonic states: my work on dysenteric infection prior to admission to mental hospitals and institutions for defectives has shown the importance of such infections as aetiological factors in both clinical conditions (Pickworth, 1927). It is known that bacteria can decarboxylate proteins, giving rise to most powerful pharmacological substances, whereas if previously deamidized by the liver the products are harmless. The action of such poisons has been studied by Ferraro and Kilman (1933) and the brain changes described. Usually toxic action upon nerve cells is histologically demonstrated by cloudy swelling, bulbous processes, alteration of staining reaction, shrinking, vacuolization, pyknosis, displacement and extrusion of nucleus, cell disappearance, and rings of phagocytic cells: special cells from the glia appear to take up the fat and debris, and may remain as scar tissue. Spielmeyer showed that there may be a purely glial response to noxious agents in bacterial infections (glial foci also occur in trichinosis).

It will, however, be evident from the preceding pages that degenerative changes in the brain parenchyma, although frequently present and contributing much to the clinical features, especially in institutions for defectives, have only a secondary relation to the actual phenomena of mental disorder, the lesions produced by destruction of nerve tissue being permanent dementia or neurological rather than psychiatric. Even a partial or reversible toxic action upon nerve cells cannot be admitted,

* Observations limited to the straight portions of pial arteries need revision following the demonstration, by Villaret, Cachera, and Fauvert, that spasmodic constrictions are localized to just beyond arterial bifurcations.

A slight ischaemia is known to increase decrement to extinction of impulse; emptying the retinal arteries by simple pressure on the eyeball causes total temporary blindness (Barnert); even electrical records of brain activity show the dependence of brain function upon an adequate capillary blood supply (Adrian, communicated privately). Penfield showed that conduction through a synapse is readily abolished by CO_2 .

In the skin and viscera, where the function of small areas is similar, a local rhythmical variation in capillarity normally occurs, controlled chiefly by metabolites. In the central nervous system, where the function of small adjacent areas is widely different, such rhythmical changes would result in confusion of conduct; and therefore this rhythmic characteristic has probably undergone in the brain certain necessary adaptations to the physiological requirements, by selective local control of the smaller vessels, not only by hormones but also by collateral impulses from higher reflexes of the central nervous system and by sympathetic stimuli; the metabolites and hormones sustaining the variations in the mosaic of capillary pattern induced by the more rapidly acting central nervous system (somewhat analogous to Creed's red tonic muscle supporting the rapidly acting pale muscle). Fig. A shows a theoretical diagram of how a mosaic of vascularized areas can determine the facilitation or inhibition of impulses from the various sensory stimuli of light, sound, etc., so that the type of motor response is conditioned by the mental or emotional state of the individual and not by the stimulus. Sherrington says that "a drug may in a second wholly reverse a reflex by tilting the inhibition-excitation balance," this phenomenon being presumably dependent upon the drug acting on the vascular supply of the synapses.

Physiological problems having an important bearing upon the mind are suggested by the anatomical distribution of fibres from a sensory organ to widely different regions of the brain. Fig. B shows the brain of a cyclostome (le Gros Clark, 1932); olfactory fibres pass from

the olfactory region both to the pineal-habenula and to the pituitary-hypothalamic regions, where function is as widely different as can be postulated. Hunger or disgust may represent an alternative choice of use of such possible reflex paths (primitive m.e.s.), and how far this choice is dependent upon the relative capillary blood supply to the respective alternate regions can be proved by direct observation, or by application of my capillary stain, in

crucial test experiments (in states of full and empty stomach, etc.). Potential m.e.s. exist without any concomitant action of the central nervous system—that is, motor behaviour—so long as no stimuli reach the controlled areas. The static quality of m.e.s. and their potential independence of the central nervous system constitute the new outlook, and are of primary importance in the correlation of the mind and its disorders with the medical sciences.

The mental and emotional states can be associated, and in my opinion identified, with the cortical (not only pia mater) capillary

mosaic pattern, which provides an efficient mechanism for the actual control of the patterns of synaptic junctions of the 12,000 millions of neurones of the central nervous system. This materially simplifies the bewildering numerical possibilities of interneuronal connexions, which we are told far exceed seconds in geological time or atoms in the universe, and reduces the number to that which experience leads us to expect by variation of sections of the cerebral capillary mosaic.

Physiology and Biochemistry of Synapses and Cerebral Vessels

Woollard has shown us that systemic vasoconstrictor nerves have two origins: (1) proximal from the sympathetic ganglia, and (2) distal by way of the somatic nerve trunks. Villaret, Cachera, and Fauvert (1937) have recorded photographically actual spasms of pial vessels. Stimulation of the sympathetic groups of fibres on the large vessels of the brain has a local or proximal effect upon arteries rather than a general distal effect on the ultimate distribution of the arterioles, and it is possible that the central nervous system contributes locally to the

FIG. A.—1 to 9 are neurones in sensory path and a, b, and c motor neurones. The synapses are collected in areas A to E. Area C transmits (dotted lines). If area B instead of C transmitted, then the same impulses would either be lost or would excite a different motor cell; other impulses—1, 2, and 5—would also excite b.

Sensory impulses are related to conduct through mental and emotional states, here shown as a vascular control of synapses in areas A to E.

FIG. B.—Brain of cyclostome. Olfactory impulses reach two brain areas of widely different function.

The posterior cerebral artery supplies the walls of the third ventricle, a large part of the thalamus, and the choroid plexus, as well as the visual cortex; in conditions of atheromatous restriction of the vertebral or basilar lumen an activity of those brain areas supplied by the posterior cerebral artery necessarily depletes the blood supply of the medulla, according to Ricker's peristasis theory with Hiller's corollary (Pickworth, 1937). This might result in an ischaemia of the vital centres which must at all costs be avoided, and so activity of the posterior cerebral artery becomes physiologically inhibited. As the control is not (as one would suppose from its morphology) from the vertebral plexus, but from the carotid plexus via the small communicating arteries (Williams, 1936), such vital implications may very well keep the unfortunate sufferer fully occupied with his internal complications—social activities and even feeding instincts becoming unimportant by comparison. A simpler case of spasm of vessels to vital centres probably occurs in reflex pain of toothache, and might be correlated with the associated mental condition of irritability and incapacity.

Ischaemia of peristatic or pathological origin results in confused behaviour and permits working sections of the cerebral capillary mosaic to be wrongly associated with normal or unrelated sections. During such pathological disturbances an untimely activity of, say, the gonads or pituitary secretions upon local sections of the cerebral capillary pattern can reasonably be supposed to be the cause of obscene language not infrequent in mental disorder cases—that is, however inappropriate with regard to external circumstances, the conduct is nevertheless appropriate to the internal but untimely demands of the individual (*Hamlet*, IV, v. 8). Conversely, it is known that frequent changes of m.e.s., as by multiple interruptions of conditioned reflexes in dogs, cause neurasthenia; and examples are only too numerous where a continued repetition of changes of mental content (such as occurs at puberty and the menopause, and in alcoholic indulgence, remorse for crime, or enforced study), when reinforced by bad training, digestive derangements, or a bacteraemia from local septic conditions, has resulted in a derangement of the cerebral capillary pattern and thus a pre-determined behaviour characteristic of mental disorder.

Mental disorder can therefore be identified with a mixing up of normal and abnormal capillary mosaic patterns. Fragments of some pattern may be assumed to persist coincidentally with fragments of other capillary patterns, in which case a stimulus reaching the brain results in a behaviour corresponding with the predominant type of pattern (that is, the m.e.s.), coloured by other fragmentary patterns also existing at the same time.

Military discipline builds up an m.e.s. which enables a soldier in war-time to obey orders an untrained civilian could not, and typifies the automatic robot-like response to command which I have tried to show is determined by the capillary mosaic regulating synapses, and therefore conduct. Persistent m.e.s. result not only from training but from pathological changes. It is obvious that when one alternative of two synaptic areas is facilitated by hyperaemia the other is relatively inhibited. In the excitement of sport an injury may be temporarily unnoticed. Excitement, shock, and fear inhibit pain. A mental patient with pathological fixed inhibitive states can actually evulse an eye or testis with little if any shock or pain; and the usual temperature response to lobar pneumonia or pyrexia-producing drugs is sometimes temporarily absent in the active phases of mental disorder.

At post-mortem examinations of mental patients yellowish areas can be found contrasting with the normal reddish capillarity in the cortex and basal ganglia. These yellowish areas are macroscopic confirmations of ischaemia which is revealed by my capillary stain. This stain discloses not only such gross irregularities of blood supply but also indicates slight differences in the vascularity of local areas, or cortical layers, which I have endeavoured to show have some physiological significance. (Injection methods cannot be used for this purpose, as they are unreliable with respect to incomplete filling in some cases and over-distension in others.) Gross local variations of the blood supply and the pathology of the vessels themselves have been described in my previous publications. The sections (Special Plate) from recognizable brain regions are given to show relative differences in vascularity of the same section, the thickness of the selected areas being in each case controlled by stereoscopic comparison: it is generally possible to use parts of the same brain for normal control. Fig. 1 (Special Plate) shows three selected areas from a section of the frontal cortex; it demonstrates hyperaemia (A), normal (N), and ischaemia (B) in a case of epileptic insanity aged 15; ganglion cells are also revealed. Fig. 2 shows a vascular area (A) and an ischaemic area (B) from a section of the motor cortex of a case of delusional insanity aged 68. (Compare also the size of the giant Betz cells seen in the lower part of both photographs with the relative capillarity.) Fig. 3 shows the occipital cortex of a case of schizophrenia: note the relative vascularity of the two areas A and B. The section also shows cells and demonstrates the band of Gennari. Fig. 4 illustrates the cortex of two contiguous lobules of the cerebellum, and shows an obvious difference in their vascularity: I have noted a rarity of gross lesions of the cerebellum—in contrast to the cerebrum—in mental hospital patients, but my technique reveals a pathology long expected but not previously demonstrated. The clinical significance of regional vascular irregularities, however, needs many more years of further patient study.

The study of mental disorder therefore becomes somewhat changed by the new outlook I have put forward. Histological lesions of the central nervous system are to be regarded as of only secondary importance to changes in the mediator of alternate higher reflex paths which I have correlated with the cerebral capillary blood supply to the synapses. Similarly more hopeful lines of treatment can be adopted: (a) preventive, by avoidance of, or by skilled nursing during and after, known causes of capillary pathology (head trauma, acute and chronic infections, dietary deficiencies and irregularities, digestive upsets, food poisons, undue excitement, etc.), and not excluding ante-natal care; and (b) in established cases by attention first to the probable cause (for example, chronic sepsis—Graves, 1932; Watson-Williams, and others) and then by a more scientific study and application of drugs and treatments known to affect the capillarity of local brain areas.

Examples of the latter are seen in Poole and Nason's (1935) work with ergotamine causing contraction of dural vessels (its action on pial vessels is irregular), which has been used with success by M. O'Sullivan (1936) for the cure of migraine; Royle (1932) cured incipient insanity by cerebral sympathectomy in suitable cases; Graves's case (personal communication) of ligature of one jugular vein for mastoid complications showed immediate mental improvement, which has been maintained; C. Adler (1936) has used barbital with caffeine successfully for epilepsy; W. F. Duggan (1937) treated tobacco amblyopia with repeated injections of nitrites and acetylcholine; Barber and Tietz

because of the difficulty of explaining in such terms the lapse into the identical disordered mental state, which rapidly follows the lucid interval produced by artificial cerebral stimulation (or excitement in the case of alternating normality and senility quoted). Friedemann and Elkeles (1934) have shown that absorption of toxins by the brain from the blood only exceptionally occurs (with such powerful toxins as cobra venom and lamb dysentery toxin) under normal conditions owing to the perfection of the haemo-encephalitic barrier; but the action of intestinal and other toxins upon the *vascular supply* of the brain is supported by many concordant observations. The above-mentioned toxic effects upon nerve cells are also seen in simple anoxia, and therefore should be considered secondary to an ischaemia induced by the action of toxins upon the smooth muscle of the capillaries.

The toxin responsible for brain changes in general paralysis is said by Neuberger, Metz, and Wilders to act on the cerebral vessels; and Merritt, Putnam, and Campbell (1937) say that degenerative changes in general paralysis may be regarded as secondary to anoxaemia from endarteritis of the small vessels. Alcohol, well known in its effect upon the m.e.s., hitherto has been considered to act upon the ganglion cells, but Thomas has shown (1937) that it has a primary action upon the cerebral blood vessels. Orr and Sturrock (1922), by placing staphylococci in contact with the common carotid, found lesions in the distribution of the cerebral arteries *primarily vascular* in nature. Even the clinical features of toxic action, such as loss of strength, loss of weight, digestive disturbances, increased pulse rate, dry tongue, flushing, pallor, circulatory disturbances of the skin, and peristaltic unrest, are indicative of primary action upon the capillaries of the metabolic centres rather than upon nerve parenchyma. The immunity of the ganglion cells of the central nervous system from prolonged toxæmia is demonstrated by dementia praecox cases, where over many years' duration the presence of circulating toxins, resembling ergot or histamine poisoning (Bayard Holmes), is evident from a study of the vascular system; the brain, however, shows no distinctive gross lesion, and Freeman (1933) speaks of the dementia praecox brain as being "particularly normal." The toxin-inhibited neurone theory must therefore give place to the better-substantiated theory of primary toxic action upon cerebral capillaries. Meyer (1936) and others support this opinion in relation both to selective vulnerability and to many pathological findings in mental deficiency, Spielmeier also having emphasized the importance of an effect via the vascular system.

Action of Endocrine Secretion

"All living cells give off substances into the blood stream which influence the others so that internal secretion is a fundamental vital phenomenon as old as the vascular system itself" (Cowdry, 1934). About two dozen hormones are known which have their action through the vascular system, but little study has yet been made of their selective action upon the capillaries of the reacting organs. Hypothyroidism is associated with fibrotic ischaemia of the thyroid gland, and hyperthyroidism with hyperaemia—and therefore hyperactivity—use being made of this in the local application of ice (generally limited to shortly before surgical operation). The specific hormones of the pituitary which influence growth and activity of the adrenals, the thyroid, and the mammary gland in all probability have a selective action upon the smooth muscle elements of

the capillaries of the respective glands (Jones, 1936, has shown that the capillaries consist of innervated smooth muscle). In practice hyperaemia of the mammary gland is induced by frequent bathing with hot water, with satisfactory results. The recent finding of many closely related adrenaline-like substances and pituitary hormones contributes to the specificity of local capillary reaction in both systemic and cerebral circulations. Schmidt (1935-6) observes a differential response of the cerebral capillaries to the action of pituitary hormones.

The relation of endocrine secretion to the m.e.s. is only vaguely understood, but the new outlook I have put forward has materially simplified the problem. The normal changes of capillary pattern corresponding to the m.e.s. are to some extent dependent upon the selective reaction to the presence of endocrine secretions which Schmidt has shown. Clinically, fear is associated with mobilization of adrenaline; the injection of sex hormone into animals deprived of gonads and genitalia induces sexual behaviour; a moral degradation accompanies some cases of dyspituitarism, precocity occurs with pineal tumours, sluggishness in myxoedema or adrenal insufficiency, and anxiety at the menopause. Advanced endocrine disturbances are only occasionally found in mental hospitals, but minor endocrine disturbances are universally present—limited only by the clinical acumen and enthusiasm of the observer. Fluctuations in the size of the thyroid (girth of neck) are observable in the cyclic states, and the pituitary gland is sometimes involved in septic extensions from chronic sphenoidal affections (Pickworth, 1935).

Hormonic action upon cerebral capillaries, being thus of primary physiological importance in normal changes of the local cerebral capillarity corresponding to the m.e.s., may later be shown to cause at least some of those pathological disruptions of the cerebral capillary mosaic associated with mental disorder. At present, however, we can only assume that some other pathological causes are primary, and that mental symptoms are then intensified by abnormal endocrine activity (such as mania in Graves's disease, and resembling the unmasking of latent character traits by the influence upon the cerebral capillaries of over-indulgence in alcohol).

Pathology of the Cerebral Capillary Pattern

Subdural haemorrhage illustrates simply the inhibitions related to certain motor cortical areas, and subcortical tumours—those symptoms of psychiatric nature, both the results of pressure ischaemia; such symptoms of incipient insanity can, and have been, cured by simple removal of the tumour, and cortical ischaemia symptoms relieved by evacuation of the clot.

Pathological disruption of the normal capillary patterns results from abnormal accumulations of metabolic products when stimuli are continued in spite of poor local blood supply (worry); from chronic pain stimuli (toothache, sinusitis); from bacteriaemia of saprophytic organisms which lodge in cerebral capillaries (focal and intestinal sepsis—Pickworth, 1935); from haemorrhages, near-by necrotic foci, and tumours; and from head trauma (commotio cerebri). Pathological ischaemia occurs by reason of spasm, oedema, diapedesis, capillary haemorrhages, emboli, or thromboses—commonly found in brains from mental hospital cases. A limitation of blood flow to large areas is imposed by atherosclerotic lesions, aseptic meningitis, tumours, chronic subdural haemorrhages, and cardiac decompensation; while hyaline degeneration in the vessels, perivascular cuffing, and intimal thickenings reduce local respiratory exchange.

illustrate these immediate post-operative changes as they occur in one plane. Fig. 1 (Special Plate) is reproduced from a radiograph which was taken immediately after the aspiration of six pints of pus from the left side of the chest and the injection of a little air in order to demonstrate the level of the fluid.

Choice of Drainage Point

The line of inflammation at the union of the visceral and parietal walls of the cavity may be called the healing edge. If this line be considered as a circle, then, it might be supposed that healing would occur centripetally at an equal rate at all points of the circumference and that the ideal position of the drainage opening would be at the centre. In practice the line of union is usually irregular, but an accurate appreciation of the shape of the cavity before operation is nevertheless a guide to the choice of the point for drainage, which is most nearly equidistant from all the parts of the healing edge. The simple conception of an empyema of circular shape healing centripetally is a useful one in so far as it emphasizes the difference between the healing of an empyema and that of a simple abscess in the cellular tissues. It is, however, inaccurate in detail for a number of reasons. First, as stated above, the outline of an empyema is seldom circular; secondly, healing does not take place in a flat plane as on a sheet of paper but along the curved plane of the chest wall; and, thirdly, because inequalities in the elasticity of the walls make the rate of healing vary at different points. The second and third of these reasons require further elaboration. If the chest wall were quite rigid and the lung perfectly expansile, healing would occur along the curved plane of the chest and there would be complete re-expansion of the lung without any collapse of the chest. This end can be attained in the treatment of acute empyema if the chest wall is prevented from collapsing by the proper exercise of muscular control. All the walls of a chronic empyema may be equally rigid owing to the dense lining of fibrous tissue, and if such a cavity can be made to heal by simple drainage it may happen that the chest wall will collapse to meet the lung as much as the lung expands to meet the chest. In these circumstances healing may occur in a flat plane. If the walls of a chronic cavity are so rigid that obliteration is impossible after simple drainage, then the chest wall must be mobilized, and healing occurs along the plane of the rigid collapsed lung.

The third consideration is closely bound up in the principle of the second. Inequalities in the rate of healing at different points depend mainly on differences of elasticity, and these may be in either the parietal or the visceral wall. In the parietal wall the ribs and intercostal structures, the diaphragm, spine, and mediastinum may all be involved, and the rate of healing along these walls varies with their relative extensibility. Thus healing between lung and mediastinum is rapid compared with that between lung and chest wall. Differences also occur in the extensibility of the lung in different parts, and this is particularly well demonstrated in empyemata secondary to streptococcal pneumonia. In this disease the inflammation is primarily in the interstitial tissue of the lung, resolution is often incomplete, and scar tissue is formed. This may vary in extent in different parts of the lung, and therefore the ability of the lung to expand varies accordingly. It is sometimes seen that the most extensive scarring has occurred in the interlobar septum, and this

layer of fibrous tissue acts as a rigid band between the hilum and the periphery of the lung, preventing expansion. Fig. 2 (Special Plate) is a radiograph of such a case, in which a streptococcal empyema occurred as a result of post-operative inflammation of the right lung. It was drained through an opening about an inch above the lower part of the cavity and half-way between its anterior and posterior extremities. Healing was delayed in the region of the interlobar septum, so that the drainage track ultimately became almost vertical, leading from the original opening below to the end of the thickened, scarred interlobar septum above. The illustration shows the track injected with lipiodol. It also shows the dense interlobar septum extending from the hilum out to the small residual empyema space at the periphery.

Classification of Acute Empyemata

The classification of acute empyemata into the sym-pneumonic and the post-pneumonic, and the general recognition of the significance of these types from the point of view of treatment, have done very much to reduce the immediate mortality from operation, but now that this lesson has been learnt a classification should be considered which would help to reduce the incidence of chronic empyema with its associated morbidity and mortality. To this end two groups, simple and complicated, are suggested. The simple empyema is one in which no permanent structural alteration has taken place within the lung tissue, and where, with adequate drainage, the lung expands completely to fill the chest with no deformity of the parietes. Such an empyema should always heal without difficulty, and if it becomes chronic this can only be as a result of inefficient drainage. The complicated empyema is one in which structural damage has occurred in the lung to such an extent that complete re-expansion is impossible, and in those circumstances not only will there be delay in healing but this will occur partly at the expense of the parietes. The factor that interferes with expansion may be an acute process such as a streptococcal pneumonia or, rarely, a more chronic one such as an underlying carcinoma. Strangely enough, the existence of bronchiectasis, though undoubtedly a cause of slow healing, is not so inimical to complete cure as might be supposed, and the reason for this is not far to seek. When an empyema develops in a patient with bronchiectasis the accumulation of pus in the pleura takes place at the expense of the healthy easily compressible lung tissue rather than the hard fibrosed part. The latter remains more or less stationary during healing, and obliteration of the cavity occurs as the result of re-expansion of the compressed healthy tissue. The healing of a simple basal empyema is usually associated with slight elevation of the diaphragm and obliteration of the costo-phrenic sinus. This is strictly a change in the parietal wall, and would be of no clinical significance if it were not for the fact that drainage tubes are sometimes inserted into the costo-phrenic sinus and that inefficient drainage almost invariably results.

The placing of a particular empyema into one or other of the two classes depends on the detailed clinical history of the case and the bacteriological examination of the pleural fluid. The most significant point in the history is the relation of the febrile attack to the pleuritic pain. In general it may be said that if the pleuritic pain occurs at the beginning of the illness the empyema is likely to be a simple one. The commonest inflammatory disease which does not cause permanent structural damage to the

(1937) gave daily doses of ergotamine tartrate, which they found diminished suicidal, homicidal, and destructive activity (Linderman observed the converse with adrenaline injections—namely, that patients became more subjective and introspective). Such treatments offer great individual and economic hopefulness, provided sufficient further scientific study of their relation to cerebral capillary function is made to render them scientific instead of empirical: in this direction the work of the Harvard Medical School, Boston, is to be highly commended.

The work incident to this paper has been carried out for the Joint Board of Research in Mental Disease, City and University of Birmingham, generously financed by the Birmingham Mental Hospitals Committees.

It is announced that one of the main subjects for discussion at the International Congress on Rheumatism now being organized to take place in Oxford in March is juvenile rheumatism. The views of experts from other lands on this serious malady will be of great interest, and meanwhile there is available Professor H. B. Cushing's recent Blackader Lecture (*Canad. med. Ass. J.*, 1937, 37, 311) on this disease as it occurs among Canadian children. He places acute rheumatism and cardiac disease in childhood as taking "first place as a threatened danger to normal childhood and adolescence in this country," basing this upon figures which indicate that about 25,000 school children in Canada are afflicted with rheumatic cardiac disease. Professor Cushing reviews the possible means of attack upon this malady and describes the interesting results obtained at the Children's Memorial Hospital, Montreal, where for the past three years children with rheumatic cardiac disease have been treated in a special pavilion very much on the same lines as patients with tuberculosis are treated. It is too soon in the experiment for any definite conclusions to be drawn, but the entire staff of the hospital is convinced that the results obtained are measurably an improvement on those seen before this step was taken. Professor Cushing pleads for organized co-operative effort to secure recognition, supervision, and after-care of all cases of rheumatic fever. He sees the need for the improvement of social conditions, particularly as regards general hygiene and housing conditions. Thirdly, he makes the point that since relapses of rheumatic fever follow regularly on infections of the respiratory tract and of the throat efforts should be made to lessen such infections and improve the hygiene of the mouth and the throat of the community.

THE HEALING OF EMPYEMA CAVITIES WITH SPECIAL REFERENCE TO ASPIRATION AND AIR REPLACEMENT AS AN AID TO OPERATION

BY

P. R. ALLISON, F.R.C.S.

Honorary Assistant Surgeon, General Infirmary at Leeds

(WITH SPECIAL PLATE)

Since the healing of empyema cavities has been investigated by repeated radiographs with lipiodol injection, it has been apparent on many occasions that the original drainage opening, though adequate at first, has during the course of re-expansion of the lung become unsatisfactory. Healing might often have been accelerated by better planning of the drainage opening. It seems that the exact shape and position of the cavity, and the way in which the lung will expand—things upon which the position of the opening must depend—are more difficult to assess than has been supposed. Ideally the drainage tube should pass perpendicularly through the chest into the empyema at a point in the wall which would normally be the last to heal. Although the attainment of this end—a matter of the greatest importance to successful treatment—might appear to be simple, it has in fact been found to present considerable difficulty. In order to place a drainage opening accurately it is necessary to understand the way in which the obliteration of a cavity normally takes place, the factors which govern this, and how they apply to the particular case under consideration.

Factors governing Healing

Healing of an empyema cavity must be distinguished from mere diminution in capacity. When pus is first removed there is in the acute case an immediate and notable diminution in the capacity of the empyema due to the return of the displaced mediastinum, re-expansion of the compressed lung, and elevation of the depressed diaphragm; but true healing is a comparatively slow

FIG. A.—Diagram showing mediastinal displacement, compression of left lung, and depression of diaphragm by a large empyema.

FIG. B.—The results of simple aspiration.

process, which depends upon the gradual and steady adhesion of the visceral and parietal walls of the empyema. The latter results from granulation-tissue formation and fibrosis all along the line of approximation of the two walls. If the pus removed from an empyema at operation is measured and the cavity immediately refilled with an antiseptic solution it is found that the amount of fluid required to fill the cavity is usually only a small fraction of the volume of pus originally present. It would be absurd, however, to suppose that to that extent healing had taken place. Figs. A and B

TUBERCULOSIS IN INFANTS

BY

DOROTHY PRICE, M.D.

Physician to St. Ultan's Infant Hospital, Dublin; Consulting
Physician to the Royal National Hospital for
Consumption for Ireland

(WITH SPECIAL PLATE)

Differences of opinion exist regarding the prognosis of tuberculosis occurring in infants during the first year of life. Many authorities consider that there can be no recovery if the disease is contracted during this early age period. Others hold that recovery is rare. Some deny altogether the existence of infant tuberculosis. With the intention of throwing light on this subject a critical examination has been made of a series of seventy-eight cases of infants suffering from tuberculosis—cases which have been under treatment during the past four years in St. Ultan's Hospital. Of these patients sixty have died and eighteen have recovered, giving a mortality of 77 per cent.

Tuberculosis as it occurs in the infant is a special study, and differences between infantile, childhood, and adult types must be emphasized. The infant gets its infection from contact with a human being in close touch with it, usually the mother; in this case the infection is repeated and often massive. Abdominal tuberculosis is rare in the first year of life; when it occurs it is as often due to ingestion of dried tubercle bacilli from floor dust as to infected milk. The main condition, therefore, which we have to deal with is inhalation infection with primary involvement of the lung. The infant shows little resistance to tuberculous infection, partly because it cannot get away from the source and so have time to acquire immunity, and partly because its defence capabilities in general are low during these early months of life. Inherited immunity may be regarded as negligible so far as tuberculosis is concerned. The picture of infantile tuberculosis is that of a non-healed primary (Ghon) focus in the lung, and the greatest danger is that this will develop into acute miliary tuberculosis of the lung or into meningitis. Of the three stages of tuberculosis (primary complex, generalized haematogenous spread, and isolated bronchogenic phthisis) we find in infants the first stage, characterized by tremendous glandular enlargement, merging rapidly into the second stage, which in its turn is characterized by involvement of the meninges or of the lung by miliary spread. If a cavity is present in an infant it is due not to third-stage bronchogenic spread but to the breakdown of the primary focus, perifocal caseous pneumonia, and cavity formation at the site of the primary focus. Cavities, caseous and confluent caseous pneumonia, meningitis, and acute miliary tuberculosis are all fatal under the age of 1 year. Children up to 3 years old who are infected by the tubercle bacillus will show a somewhat similar but modified picture, and recovery during the primary stage is the rule rather than the exception. After the age of 3 infection becomes much less tempestuous, for the glandular defence is more successful in stopping fatal blood-stream spread; in spite of the danger of involvement of bone, joint, eye, kidney, etc., the primary complex heals in many cases without metastases. In later childhood, in addition to secondary metastases, the adult type of phthisis may be seen.

It may be asked how we knew that these seventy-eight infants were suffering from tuberculosis and not from "marasmus." It is generally accepted that a positive

tuberculin skin test in an infant indicates an active lesion. Secondly, sixteen consecutive necropsies performed at the outset of the investigation provided a criterion for the interpretation of radiographs in subsequent cases. Thirdly, a history of contact in the home was forthcoming in 70 per cent. of cases.

Analysis of the Fatal Cases

Of the sixty patients who died twenty-three were infected before they were 6 months old. The sexes were evenly divided. The following conditions were involved:

Pulmonary Tuberculosis (22 cases; 5 necropsies).—In these there was no attempt at healing in the primary focus. Localized caseous pneumonia and occasionally cavitation were observed. Duration two to three months. Broken-down primary focus.

Miliary Lungs (18 cases; 5 necropsies).—Including millet-seed acute miliary and confluent caseous pneumonia affecting both lungs; abdominal organs frequently involved. Primary focus indiscernible. Duration two to three months. Second stage, haematogenous spread.

Tuberculous Meningitis (17 cases; 4 necropsies).—All following a pulmonary lung infection: primary focus seen in fourteen cases by radiography (three were not radiographed, but one was seen post mortem). Duration one to two weeks. Second stage, blood-stream infection.

Abdominal (2 cases; 1 necropsy).—One secondary to localized lung lesion (swallowed sputum). One with lungs free, fed on milk of one tuberculin-tested cow; mother had open phthisis; ingestion from floor-dust.

Congenital Tuberculosis (1 case; 1 necropsy).—Primary focus in the liver; entry via the umbilical vein from placenta of phthisical mother.

Father	9	4
Uncle, aunt, brother, etc. ..	9	5
Not elicited	23	—

Fifty-seven deaths, then, occurred from inhalation infection, either with caseous pneumonia due to non-healing of the primary focus or in the stage of haematogenous dissemination. All these infants were seen only after the first stage had passed, with the exception of two who were admitted in the primary stage but in whom the focus broke down during an intercurrent infection (whooping-cough and Vincent's angina). A few days after admission it was possible to give a hopeless prognosis to the parents of fifty-five of these patients. By the comparison of post-mortem and x-ray findings data were provided for earlier diagnosis of tuberculosis of the lungs, and it was recognized that any hope of effecting a cure depended on diagnosis during the primary stage, before caseous pneumonia or blood-stream dissemination had set in. It is essential that healing of the primary focus be ensured; for in the

lung is pneumococcal pneumonia, and this is most often the cause of simple empyema. If, however, a febrile attack is the initial disturbance, followed after some interval by pleuritic pain, the empyema is likely to be a complicated one. Streptococcal pneumonia, and pneumonitis secondary to lung abscess and bronchial block, start in the depths of the lung tissue and spread outwards to the pleura by the interstitial lymphatics, so that pleurisy occurs at a later stage of the illness.

Treatment

With regard to the treatment of the two varieties of empyema, it may be said that in no case does preliminary

radiographs of the chest are taken in the upright position, in antero-posterior and lateral planes, sometimes one or other oblique plane, and occasionally in the prone position. From these films the best point for drainage is chosen according to the principles advanced above. The method of drainage, open or closed, is not considered to be of any importance so long as the tube is large enough and in the right place. A portion of rib is always resected. The above procedure has no influence whatever on the ultimate choice of treatment in a particular case; some are still treated by aspiration alone and some by aspiration followed by drainage, and the rules for the choice of the appropriate method are sufficiently well established to be omitted here.

FIG. C.—Diagrams showing immediate expansion of lung, rendering drainage tube ineffective.

aspiration do harm, and that in every case this simple operation relieves the patient and at the same time gives valuable information to the operator. It must be admitted that where a cavity is filled with large masses of fibrinous clot aspiration is not always possible, but the routine attempt at the above procedure has been found to diminish the number of cases requiring secondary drainage operations.

It has already been mentioned that relief of pressure in an empyema is associated with immediate anatomical adjustments within the chest, and it is obvious that these changes must result in an alteration of the shape of the empyema cavity. When empyemata have been drained without previous aspiration it has sometimes been found that these adjustments result in the lung coming up flat against the end of the tube and so interfering with the drainage of a relatively deep space. This is depicted in Fig. C. Before the point of drainage is decided, therefore, it is an advantage to allow these immediate adjustments to be made by the aspiration of as much of the pus as possible, followed by radiological examination in two or more planes.

From every point of view it is desirable, before operation, to know these details: the shape, position, and size of a cavity after the relief of pressure within it; the composition of the parietal wall; and such information about the way in which the empyema will heal as may be deduced from consideration of its nature and the elasticity of its walls. To this end it has become the practice in the treatment of these cases to aspirate through a wide-bore cannula, where possible, as much of the pus as can be removed, and then, by leaving the cannula in position while detaching it from the suction apparatus, to allow a little air to be drawn into the cavity by the patient's own respiratory effort. The presence of air in an empyema cavity is not harmful in any way, but by creating a fluid level it makes accurate radiological examination of the cavity possible. Following aspiration,

Summary

1. The way in which an empyema heals is discussed and the factors governing this are indicated.
2. The best position for the drainage tube is shown to depend on the immediate anatomical adjustments following the relief of pressure in the empyema, and on the factors influencing the way in which gradual obliteration of the cavity takes place.
3. Knowledge of these things may be gained by the routine pre-operative aspiration of pus and partial air replacement followed by radiological examination in various planes.
4. The position of the drainage opening is of the greatest importance if chronic cavities and secondary drainage operations are to be avoided.

The Cicely Northcote Trust was bequeathed to St. Thomas's Hospital twenty-eight years ago with the object of extending almoners' work into the wards, and making a comprehensive medico-social service for in-patients and their families before admission, while in hospital, after discharge, and in certain cases until death. The report of work done between October, 1936, and October, 1937, has recently been issued, and as in previous years contains numerous examples of the great value of the undertaking alike to patients and medical practitioners. The "follow-up" activities sometimes secure adequate nursing for in-patients who could not otherwise obtain it after discharge. Latterly, it is mentioned, there has been a closer linking in cases of malignant disease between the social and the medical follow-up work, especially for patients who have been treated with radium. Records of each case are kept, and prove to have statistical as well as clinical value. The scope of the work seems likely to extend, and further financial help is desirable. The Trust almoners are required to interview all patients admitted to the wards to discuss whether any contribution can be made towards the cost of treatment, or whether assistance is actually necessary to ease home difficulties.

hospital treatment, may result in cure even in such apparently dangerous cases (Plate, Fig. 2). Prognosis depends entirely on the stage at which diagnosis is arrived at, and thus every effort must be made to search out these cases and to recognize at a very early date the fact that they have been infected. The primary infection will show no clinical signs typical of the condition, and diagnosis can only be made on the grounds already mentioned.

Treatment

First and mainly treatment consists in removal of infants from all possible tuberculous contact. They should not be put in sanatoria where there are cases of open phthisis. They should be taken to infant hospitals or preventoria, and the isolation must be maintained until healing is evidenced by calcification or by fibrosis. Calcification is the less usual end-result, because if infants have caseating foci there is nearly always a fatal termination. Fibrosis is the commoner end-result; and here in later radiographs nothing abnormal is seen, and the only proof of past infection is the serial radiographs and a positive tuberculin test. Healing is established in mild cases in six months, but other cases may take up to two years. The falling of the sedimentation rate to normal also indicates healing. The second essential of treatment is rest in bed. Movements in the cot have to be permitted, but exercise out of the cot must be postponed until serial radiographs and normal sedimentation rate and weight gain show that the lung is healed. Fresh air is essential throughout treatment, but infants must not be exposed beyond their limits of endurance, and throughout treatment they must be kept warm. Digestive disturbances must be attended to and a suitable diet rich in vitamins, with added calcium, must be given. Ultra-violet rays and strong sunshine are absolutely contraindicated in all pulmonary lesions in infants and children; however, in these climates outdoor shade in summer and exposure to sun in spring and autumn are safe. Temperature charts, the sedimentation rate, and radiographs all demonstrate how dangerous is sun-bathing to a small child with a pulmonary lesion, be this only in the primary stage. It will be found that casualties occurring during the primary stage of pulmonary tuberculosis will be among those infants whose parents are not convinced, and who do not allow this treatment to be carried on until complete healing has been ensured.

Summary

1. Seventy-eight cases of tuberculosis of the lungs are reported in infants under 1 year old: 23 per cent. recovered.

2. Healing can only be achieved by early diagnosis—that is, in the primary stage.

3. Early diagnosis can only be made by tuberculin skin test, radiography, and history of contact.

4. Treatment consists mainly in immediate removal from contact and in rest.

D. Bobeff (*Mscr. Kinderheilk.*, October 8, 1937) records the case of a Bulgarian girl, aged 10, who on the sixteenth day of a severe attack of faucial diphtheria, six days after the onset of palatal palsy, developed gangrene of both legs, most marked on the right side. The necropsy three days later showed thrombosis of the abdominal aorta, multiple infarcts in the left kidney, gangrene of both feet, and myocarditis. Bobeff has found only two other cases on record of occlusion of the abdominal aorta following diphtheria.

AN UNUSUAL TUBERCULOUS APPENDIX

BY

D. J. HARRIES, M.D., D.Sc., F.R.C.S.

AND

EMRYS WILLIAMS, M.D., M.R.C.P.

Cardiff

(WITH SPECIAL PLATE)

Although tuberculosis of the appendix is not an uncommon disease it is still the exception for it to be mentioned in standard textbooks of medicine or surgery. It has been stated that from 1 to 3 per cent. of all appendices removed at operation are tuberculous. It is obvious that an investigation into this problem at a large hospital would entail an enormous increase in the microscopical work of the institution, and this might be regarded by the pathologists as out of proportion to its value. An investigation carried out by Pagel and Weichherz (1936) at Papworth Village Settlement, based on eighty-four necropsies on tuberculous subjects, showed that roughly one-third had no intestinal tuberculosis; another third had intestinal tuberculosis with no involvement of the appendix; the remaining third had involvement of both the intestine and the appendix. In three cases the appendix was the only part of the gut to be involved, and in each there was extensive tuberculosis in the lungs.

The appendix is almost always involved in ileo-caecal tuberculosis. It is generally recognized that tuberculosis may primarily involve the intestines, but it is not so certain that the appendix alone can be the site of tuberculosis. In view of the above remarks it requires some courage to suggest that the case described below is one of primary tuberculous appendicitis, successfully treated by operative removal, with the patient alive and perfectly well nearly two years later.

Case Record

On March 18, 1936, a marine engineer, aged 19 years, had a slight attack of abdominal pain lasting about an hour. It was so mild that the patient did not trouble to obtain medical attention, and in fact went on with his work. On March 23 he had a recurrence of the pain, and when seen by one of us (E. W.) was sent into a nursing home with the diagnosis of acute appendicitis. On admission the temperature was 104° and the pulse 90. There was very little rigidity but some tenderness in the right lower abdomen. On account of the comparative absence of rigidity it was possible to palpate a large tubular structure, about an inch in diameter, running from the right iliac fossa into the pelvis. It felt like an indurated coil of intestine or an intussusception. The patient and his mother were quite definite that he had never been ill before.

Operation.—This was carried out within three hours of the onset of symptoms by D. J. H., the anaesthetic being given by E. W. On opening the abdomen it was seen that the tumour was an enormously enlarged appendix, its peritoneal coat being dark red. It felt perfectly solid and hard, and there was no constriction at its junction with the caecum. After ligating its mesentery the appendix was removed intact and the raw area left on the caecum covered over by making use of the ileo-caecal fold of peritoneum. There was some induration of the wall of the caecum for about half an inch beyond the actual area to which the root of the appendix was attached, and if the tuberculous nature of the appendix had then been known this area would have been resected.

Subsequent Progress.—The patient made a rapid recovery, the temperature falling two degrees a day, and was normal on the third day. It is curious that the pulse never exceeded 90 at any time during the illness. The incision healed by

infant hypersensitivity is markedly disproportionate to the weak glandular defence. The invasion of the tubercle bacillus and the swamping nature of its course, unopposed in the infant, may lead to death within a few weeks of its first entry. Thus it would appear that all hope of cure depends on early recognition of the infection, followed by immediate removal of the infected infant from further contact. "Early" means before physical signs are established: to be on the safe side all doubtful cases should be treated as positive until the contrary is proved.

Analysis of Cases that Recovered

The eighteen patients who recovered were in the primary stage of pulmonary tuberculosis; eight were under 6 months old when first observed. All had definite radiological appearances, all had a history of family contact, and all were positive to the tuberculin skin test. Regarding the tests, twelve were positive to the percutaneous test, and the six who were negative to it proved positive to a second test—namely, a stronger dilution given intracutaneously. The position of the recovered cases to date is as follows: twelve are completely healed radiologically and are clinically well—two for a period of four years, four for three years, five for two years, one for one year; and four are still under observation but have been healed for six months. The remaining two are still in hospital after three months' treatment; their radiographs are now clear, they are gaining weight rapidly, and there is no reason to think that they will not heal completely.

Diagnosis

In these cases diagnosis was made on three grounds, and three grounds alone—namely, the tuberculin skin test, the chest skiagram, and contact history. Each case underwent repeated physical examinations, which provided no definite information; indeed, the results were often misleading. The conclusion at which I arrived was that the more one hears in an infant's chest the less likely it is to be due to tuberculosis. There is no cough as a rule, but pressure of glands on the trachea will sometimes produce a barking hoarse cough with an expiratory whoop which may be confused with pertussis. Some slight dullness on percussion and diminution of breath sounds on auscultation may be present if the infiltration is heavy, but otherwise the primary stage is silent. The later stages are also characterized by absence of physical signs. Vomiting (caused by swallowed sputum) and anaemia are sometimes present, and there is no increase in weight. Fever is usually absent.

The Tuberculin Skin Test.—This test is invaluable in detecting the primary stage. A weak dilution must always be tried first, as the infant may be hypersensitive to tuberculin. If negative the test should be repeated once a week, for the reason that an incubation period of six weeks from the entry of the bacillus must pass before the establishment of allergy, which is manifested by a positive test. The preliminary test in this series was by means of Hamburger's percutaneous ointment, which is equivalent in strength to a dilution of 1 in 1,000 intracutaneously. If this was negative, four days later 0.1 c.cm. of a 1 in 100 dilution Mantoux was injected intracutaneously. It is sometimes difficult to elicit a response in an infant under 6 months old. At times also it is not easy to get a positive response in tuberculous meningitis or advanced miliary tuberculosis, but the 1 in 100 Mantoux is usually successful.

Radiology.—The use of radiology is essential, but we must know what to look for in the film, and our inter-

pretation must be guided by the tuberculin test. We seek a primary focus in the lung field, an infiltration, and enlarged mediastinal glands. The primary focus may be concealed in the infiltration, and it is not easy to decide whether this is an infiltration of the primary stage or a caseous pneumonia; the prognosis is very different in the two. The glands involved may belong to the hilar or paratracheal groups, or both; the glands may be seen with the primary focus, or alone if the latter is small and invisible by x rays. Sometimes the glands do not appear as discrete entities, but as a ribbon shadow on either side of the trachea (Fig. 1 on Plate): in this case the shadow is caused by vessels which are displaced by glands; the error of taking the film during the phase of full expiration will give a false impression of a ribbon shadow. Transitory enlargement of hilar glands occurs in bronchitis and pneumonia, but a negative skin test and repeated radiographs will settle this point. Lateral views are useful in showing up the bifurcation glands. In infants one must not look for calcification, and healing by fibrosis will not produce the striation seen in adult films. The primary infiltration involves part or all of a lobe, or even a whole lung, in an infant. It may disappear in a short time, but it can remain for over two months. Its nature is that of a non-caseous exudation. The shadow seen in cases of epituberculosis lasts much longer than two months, and is, on the whole, somewhat denser, which is to be expected if this transitory tissue reaction, which is without caseous changes, is accompanied, as is often the case, by atelectasis due to occlusion of a bronchus by plugging or by compression. None of the above series showed epituberculosis clinically, radiologically, or at necropsy; the condition appears to occur more frequently during the second and third years, as well as in older children.

History of Contact.—It is most important, especially when a parent is involved, to obtain the contact history. This matter has been dealt with fully by Gregory Kayne in his exhaustive article "Tuberculosis in Home Contacts" (*British Medical Journal*, 1935, 1, 692). But chance infection also plays a part. A newborn twin in a maternity hospital was lent by the nurse to comfort a woman who was very ill and had lost her own baby. This baby, aged 16 days, was sent to our hospital as "delicate," and he died of miliary tuberculosis of the lungs when 6 months old; the other twin and the rest of the family were free from tuberculosis. In the accompanying contact table the twenty-three cases where no history was elicited were not investigated personally, so I cannot vouch for them as having no history; it may have been a remote one.

Prognosis

When the diagnosis is made in the primary stage prognosis is favourable provided that the infant is immediately removed from contact. Protection from intercurrent infection is also most important. The prognosis is fair when the primary infiltration is localized and the hilar glands only are involved: then the tuberculous process will probably heal, but if the baby is very young no certain prognosis can be given. The prognosis is much less favourable when the lung shows a widespread infiltration or when a caseous pneumonia is commencing, or if there is massive involvement of the paratracheal glands. Infection of the paratracheal glands rings a note of grave warning, for at any moment these glands may discharge their content of tubercle bacillus into the blood stream: this takes place via the thoracic duct, and leads to generalization and metastases. Nevertheless removal from contact, with

bodies of the sacral vertebrae until it is felt to recede at the lumbo-sacral angle being plainly impossible in all but a grossly contracted pelvis. The error of position of the fingers can be readily proved by attempting internal pelvimetry with radiological control, using a piece of lead in the glove tips of the index and middle fingers. The lead shadow will be seen to be well wide of the mark, even when the perineum is forcibly depressed.

The third factor is the rigidity of the perineum, and, as the type of case in which we most earnestly desire to measure the true conjugate is usually a primipara, this assumes major importance and demands an anaesthetic of reasonable depth, at least, for its removal.

Lastly, the measurement is likely to be of most use in those cases of minor contraction, and these are the very cases where, for the reasons above enumerated, it is most difficult or impossible to obtain.

Conclusion

The conclusion is that the clinical measurement of the true conjugate is either impossible to measure, or inaccurate when measured, in all but cases of severe pelvic contraction; that a genuine attempt to measure it demands in a primipara a full anaesthetic; that the location of the sacral promontory requires practice and skill and is valueless unless performed by one well versed in pelvic examination; and that the measurement, when truthfully obtained, is open to considerable experimental error, in addition to errors due to the particular anatomy of a given patient, such as the depth and inclination of the symphysis.

WHY "POST-ANAESTHETIC" PULMONARY COMPLICATIONS?

BY

G. R. OSBORN, M.B., B.S.

Pathologist, Derbyshire Royal Infirmary

That the great majority of "post-anaesthetic" pneumonias are "post-anaesthetic" in time relation only is no longer open to doubt. Inhalation anaesthesia does not predispose to pneumonia unless there is pre-existing lung disease. The typical post-anaesthetic pneumonia is the result of many minute pulmonary emboli from the operation site, and so is slightly commoner after local than after general anaesthesia. Its most important causes are trauma, mobility of the affected part, and sepsis (Cutler and Hunt, 1922). The control of "post-anaesthetic" pneumonia is thus mainly in the hands of the surgeon, not the anaesthetist. The term is therefore deplorable, because it diverts attention from the real causes and possibly suggests negligence on the part of the anaesthetist.

Aspiration of Foreign Matter in the Trachea

Very interesting observations on the ease with which matter such as blood and mucus enter the trachea have been made by M. C. Myerson (1922); he demonstrated it in 76 per cent. of patients who had had a tonsillectomy under light general anaesthesia, a cough reflex being present. Ochsner and Nesbit (1927) made an even more striking demonstration by placing lipiodol in the mouth of patients who had local anaesthesia of the tonsillar region. Radiographs taken later showed that lipiodol had

passed into the lungs in every case. The same thing happens readily in patients who have pharyngeal anaesthesia as a result of disease.

AN ILLUSTRATIVE CASE

Recently I made a necropsy on the body of a woman of 65 who drowned as a result of taking a cup of tonic (sanatogen) directly into the trachea. A small amount of fluid had entered her trachea on many previous occasions; she was known to have a syphilitic paralysis of the palate. Her body was slightly wasted and cyanosed; the blood was dark and fluid; she had a syphilitic aortitis and aortic regurgitation. There was no obvious pre-existing lung disease. The bronchi were filled with a whitish frothy emulsion, which was not readily distinguishable from pus by the naked eye. Microscopically its nature was clear, but a considerable amount of the sanatogen had been taken up by phagocytic cells. Routine sections showed no bronchopneumonia. There was no post-mortem evidence of the many small amounts of foreign matter which had entered her trachea on previous occasions.

It therefore seems certain that the cough reflex fails as a mechanism of expulsion under light anaesthesia; also that blood and mucus do not appear able to provoke pneumonia by themselves. It is not suggested that foreign matter can enter the lungs with impunity, for that is obviously not so. A typical example of this was a woman of 46 who was rescued from a suicidal attempt in a canal recently. She was resuscitated fairly easily, and was hysterical when admitted to the Derbyshire Royal Infirmary. For some hours she made good progress, but pulmonary oedema developed and she died about thirty hours after jumping into the canal. At necropsy I found a simple acute inflammation of the larynx and trachea, generalized pulmonary oedema, patches of red hepatization indicating early bronchopneumonia, no evidence of pre-existing lung disease, and a normal heart. In this case the cause is clear: it was neither "post-anaesthetic" nor due to embolism. Such cases are not rare, and they serve to emphasize the danger of regarding complacently the blood and mucus which enter the trachea far more readily than most of us realize.

General Anaesthesia as a Cause of Lung Abscess

The role of general anaesthesia in the aetiology of lung abscesses after tonsillectomy has been variously estimated. The usual belief is that the condition is commonest after open general anaesthesia and rare after intratracheal ether or other types of general anaesthetic in which special care is taken to prevent foreign matter entering the trachea. The average incidence is probably 1 in 2,500 tonsillectomies (Moore, 1922), but figures vary from 1 in 358 (Glowacki, 1923) to 0 in 20,000 (Lyman, 1923). A. L. Lockwood (1923) found that out of 208 lung abscesses 201 followed general anaesthesia. M. Manges (1916) noted that lung abscesses were commoner after operations with the patient upright. J. Maxwell (1934), in an exhaustive study, however, finds that the main association is sepsis in the operation field, and favours an embolic origin: such a view frees the anaesthetic from both direct and indirect blame. He also notes that lung abscesses are commoner after tonsillectomy than after dental operations. I have recently made two necropsies which throw some light on the problem.

TWO ILLUSTRATIVE CASES

Case 1.—An emaciated boy of 4 years had a lower left molar tooth removed on October 2. An abscess about five days old was present. The anaesthetic used was an ethyl chloride spray, and the boy did not lose consciousness. He

first intention and the patient went home on April 8, a fortnight after the operation. He has been seen and examined several times since. In February, 1937, he served as second engineer on a trip to the East, and returned in June. He was then carefully examined by us, but nothing abnormal could be found in the chest or abdomen. In fact he felt and looked perfectly well.

The Specimen.—Before hardening in formalin this was six inches long and one inch in diameter, and slightly curved. It was quite solid and hard, with a small black spot representing the original lumen. The cross-section at the root was greyish pink, with no evidence of necrosis or suppuration—in fact, the only sign of inflammation was in the peritoneal coat, which was dark red. The specimen, which has been placed in the museum of the Royal College of Surgeons, is now smaller and the colour of the peritoneum has faded. Fig. 1 (see Plate) shows the size and shape after hardening and mounting. Fig. 2 gives the microscopical appearance of a section taken from the cut surface at the root. A few giant cells can be seen in a mass of lymphoid tissue. The various layers normally found in the wall of the appendix have been completely replaced by tuberculous tissue, the peritoneum alone having survived.

Comments

It is unnecessary to state that the exact nature of the change in the organ was not realized until the microscopical slides were examined. The specimen was unlike any appendix we had seen previously. It is obvious that the disease must have started months, if not years, before it was discovered. The absence of symptoms until within three hours of operation allowed us to remove the specimen before it had been damaged by inflammatory processes. We are of the opinion that the acute symptoms were caused by interference with the blood supply, as there was no visible lumen which could have been infected. At the operation the other abdominal organs were looked at in the ordinary way, but nothing abnormal was found. It must be admitted that small tuberculous lesions were not specially sought, as the diagnosis of tuberculosis had not then been suspected. But in view of the subsequent history of the patient it is reasonable to assume that there could not have been any well-developed tuberculous changes in the intestines or lungs. He returned to work in a few weeks, and has since enjoyed perfect health.

We are indebted to Mr. W. J. Salter, technician to Llandough Hospital, for the photographs.

REFERENCE

Pagel, W., and Weichherz, E. (1936). *British Medical Journal*, 2, 1305.

La Migraine Ophthalmique, by Drs. G. Renard and A. P. Mekdjian (the publishers are Masson of Paris and the price is 22 francs) gives a convenient summary of what is known of migraine, well set out under carefully designed subheadings. No unifying conception emerges, the authors stressing the multiplicity of associated disturbances, and dealing in particular with the allergic basis of the affection. One point of interest which they bring out is the disturbance in blood pressure, which they studied both from the general aspect and by ophthalmodynamometry of the retinal vessels. In general they found a tendency to hypotension during the attacks. Their thesis is illustrated by some case reports. They argue that hypotension can be taken as a diagnostic feature distinguishing true migraine from the transient blotting out of vision seen in elderly people with hypertension. They regard migraine as a condition which, though distinct from epilepsy, has in common with it the fact that there is a widespread, though ill-defined, underlying general departure from the normal, both psychological and somatic.

PELVIMETRY AND THE TRUE CONJUGATE

BY

JOHN HOWKINS, M.D., M.S., F.R.C.S., M.C.O.G.

Obstetric Registrar, the Middlesex Hospital

Every obstetrician must from time to time have been asked to see ante-natal cases in which a practitioner or midwife has felt on vaginal examination the sacral promontory; and there must be a number of women who are, because of this genuine misconception, submitted to unnecessary obstetric operations, with a diagnosis of gross pelvic contraction.

While not decrying the academic importance of attempting to measure the true conjugate clinically, it is the purpose of this brief communication to draw attention to the extreme rarity with which the sacral promontory can be palpated per vaginam; and my excuse for burdening an already adequate literature is that in the course of the last twelve months' ante-natal work three cases have been referred to the Middlesex Hospital Ante-natal Clinic labelled with such a phrase as: "Sacral promontory felt per vaginam: ? Caesarean section for pelvic contraction." All three were subsequently delivered by the natural passages. The only explanation that answers this fallacy is that the "sacral promontory" is in reality one of the lower bodies of the sacral vertebrae.

Three Factors to be Considered

Whether or no the sacral promontory is palpable depends on three factors: first, the length of the true conjugate; secondly, the effective length of the examining finger; and, thirdly, the rigidity of the vaginal introitus, which largely depends on the co-operative relaxation of the patient and her parity.

The anatomical true conjugate on the average female dry bony pelvis measures between 4.25 and 4.5 inches: the distance of the point behind the symphysis, from which the true conjugate is measured, to the subpubic angle is 1 inch on the bone, and must be nearly 50 per cent. greater than this when measured to the anterior lip of the vaginal introitus, in order to take into consideration the triangular ligament and its associated superficial small muscles and soft structures. This latter is greatest in the primipara and least in the multipara, for obvious reasons. Applying the well-known principles of geometry, the total effective length of an examining finger must be roughly 4.75 inches to feel the promontory in a normal pelvis.

The effective length of the examining finger, assuming that the index and middle fingers are used together, varies slightly with different surgeons, but surprisingly little. The determining factor here is largely the resistance encountered by the ring finger knuckle against the perineum, and to increase this useful length the perineum must be pushed upwards and backwards. Discounting this last factor, the uncompensated effective length of one's fingers is about three and a half inches. In a normal pelvis, therefore, with a true conjugate of 4.5 inches, the finger must be lengthened by depressing the perineum at least 1.25 inches before the promontory is reached, or, conversely, the pelvis must be foreshortened down to a true conjugate of 3.5 inches before the tip of the middle finger is likely to meet the posterior bony landmark. The exact location of the promontory is, moreover, a matter of difficulty, the manœuvre of sliding the finger up the

fairly steady but there was a gradual increase in myeloblasts. The clotting time was 7.5 minutes (normal 5 minutes), and the bleeding time 14 minutes (normal 1-3 minutes). Albumin was occasionally present in the urine, and the excretion of uric acid was increased from 40 mg. to 59 mg. per 100 c.cm. Films prepared from material obtained by sternal puncture showed eosinophil and neutrophil polymorphs and myelocytes, but the most prolific cell seen was about twice the size of a red cell, with a large, rounded, pale nucleus and non-granular cytoplasm. Repeated stereoscopic radiographs of the skull showed no periosteal reaction in the affected orbit, even when the tumour had attained considerable size. Films of the thorax revealed no bony changes in the ribs or sternum, and the lung fields were clear apart from slight increase in the bronchial markings.

TREATMENT

Treatment was undertaken in a spirit of pessimism. In view of the blood count the patient was given weekly injections of 3 c.cm. of Lilly's liver extract (conc.), and a mixture of ferri et ammon. cit. 20 grains with liq. arsenic. 3 minims, three times daily. It was thought that copper might be a helpful medicament both for its synergic action with iron in influencing the anaemia and also for its supposed anti-malignant effect. The patient was therefore given 3 c.cm. of Crookes's collosol cuprum intramuscularly three times in the first week and thereafter once weekly.

On September 24, as the haemoglobin had dropped to 15 per cent. and the patient's general condition was critical, she was given a transfusion of 1,000 c.cm. of whole blood, and there was a rapid general improvement. The next day the spleen was palpable for the only time during the illness. On October 23 x-ray therapy was commenced, directed to the orbital tumour. The radiologists give the following details: 300 r daily for five days; factors, 200 kV 8 mA, filter 1 mm. Cu plus 1 mm. Al; focal skin distance, 50 cm.; field, directly over orbit, 7.5 cm., round cone. Although the orbital tumour decreased in size the patient's general condition gradually deteriorated, and she died on November 1.

POST-MORTEM EXAMINATION

The pericardial sac contained fluid in the form of greenish foam. The endocardium showed a thrush-breast appearance. The spleen measured 8 in. by 4 in. and was normal in appearance. The kidneys measured 6 in. by 3 in. and exhibited dark macular areas. The ovaries were normal in size but bright green throughout. There was free fluid in the peritoneal cavity, and there were very numerous enlarged mesenteric glands; the liver surface showed small green areas, and on section a typical nutmeg effect was seen. The pancreas showed numerous green areas. The brain was normal, but there was considerable extradural and intradural fluid. The adrenals appeared normal. The orbital tumour was a green mass, about the same size as the eyeball, and was attached to the bone. The whole of the posterior surface of the sternum was covered by a thick mass of green tissue.

Pathologist's Report

I am much indebted to Dr. F. B. Smith of Preston for the following detailed report:

NAKED-EYE APPEARANCES

1. *Eyeball*.—With all contents of socket. At one side is a thick disk of green tumour $1\frac{1}{2}$ by $1\frac{1}{2}$ by $\frac{1}{2}$ in. with fragments of bone adherent to its outer surface. Consistence of tumour even and elastic, like that of the sternum.

2. *Sternum and Rib Cartilage*.—Whole of posterior surface of sternum covered by flat yellow-green tumour, of uniform consistence, rubbery, and a quarter of an inch thick: smooth even surface. Extends slightly into the rib cartilages. There is a similar but smaller flat tumour over the lower half of the front of the sternum. The periosteum is part of the "neoplasm," which strips smoothly off the bone.

3. *Piece of Heart Muscle*.—Shows a few petechiae on the outer surface.

4. *Piece of Liver*.—1 by 1 by $1\frac{1}{2}$ in. Pale brown with distinctive yellow mottling.

5. *Wedge of Spleen*.

6. *Piece of Kidney*.—Transverse slice of one-half of a kidney half to one inch thick, capsule absent: surface slightly nodular, some elevations red, others yellow-green.

7. *Slice of Pancreas*.—Shows small green patches.

8. *Appendix*.—Four inches long, normal external appearance.

9. *Ovarian Cyst*.—Opened. Flat diameter $1\frac{1}{2}$ inches. Inner lining pea-green, and patches of the same colour on the outer surface.

10. *Mesentery*.—Contains one calcified gland and many small glands. Faint green colour in patches in the connective tissue but not in the glands.

11. *Chain of Abdominal Glands*.—Marked hyperaemia and bright green colour of all surrounding connective tissue.

12. *Shaft of Femur: (1) Split, (2) Unsplit*.—Six inches. Marrow uniformly red. The sawdust is distinctly green.

HISTOLOGICAL NOTES

1. *Orbital Tumour*.—The sample contains a large lobule of lachrymal gland, embedded in fibrocellular and fatty tissue. The "tumour" has a fairly rich supply of blood capillaries. There is cellular infiltration of the fibroblastic tissue, mainly diffuse, evenly distributed, but with isolated closely packed columns of cells between fibrils of stroma. The cells are of widely varying shape but uniform size of about 10 to 15 microns: spherical or polygonal, with more nuclear substance than cytoplasm. The cytoplasm is non-granular when stained with haemalum and eosin. The nuclei vary widely in shape, being spherical, elongated, and slightly folded, or bilobed, or double: the nuclei are hyperchromatic and show coarse granules and strands of chromatin. Nucleoli are not seen. The design under the low power is diffuse fibrosis, with moderate and diffuse infiltration by cells indicated. These cells invade freely the interacinar stroma of the lachrymal gland.

Orbital Plate.—Attached to the outer surface of the orbital tumour is a thin plate of bone. This, after decalcifying, shows cellular design and features the same as the above, though fibrosis is greater and bony trabeculae are thin and widely spaced.

2. *Sternal Tumour*.—This is a densely cellular lesion—a closely packed mass of infiltrating "chloroma" cells, compressed between a thin superficial capsule and the bone surface. Stroma is scanty, but is visible between layers of cells only one cell thick. The periosteum is only recognizable by detached flakes of bone. In capillaries is a dense aggregation of undistorted cells, resembling those seen in films of the blood taken before death. Fresh films of sternum tissue stained for oxidase by the Goodpasture technique show a considerable proportion of large mononuclear cells giving a positive reaction.

3. *Heart Muscle*.—Many capillaries are packed with "chloroma" cells, which also are thinly scattered in inter-fibrillary spaces, with a few small perivascular aggregations.

4. *Liver*.—Gross fatty change, with survival of thin bands of parenchyma in the periphery of lobules. Widespread permeation of sinuses and perivascular portal sheaths with "chloroma" cells.

5. *Spleen*.—General design preserved: for example, Malpighian nodes are prominent, numerous, and of normal cellular structure; but the pulp is densely packed with "chloroma" cells.

died nine days later. There was a foul osteomyelitis of the left side of the jaw, pus from which extended into the cellular tissues of the neck, but no mediastinitis was found. The lower lobes of both lungs were almost completely solid from a very large number of small abscesses. In the left upper lobe there was a broken-down abscess three-quarters of an inch in diameter, which may have been older than the others. The pus in all the abscesses was very foul. No tooth-fragment could be found though a careful search was made, and this would have been a relatively easy case in which to discover it had it been present. The heart and other organs were normal. It appeared clear from the distribution that these abscesses were the result of inhaled septic matter. It is possible that the basal abscesses were secondary to the one in the left upper lobe, but the history does not support that suggestion. It is difficult to imagine an anaesthetic less likely to favour inhalation of septic matter than a brief ethyl chloride spray. The boy was reasonably well for several days, and then his mouth began filling up with pus, which was very offensive, but which he could not be persuaded to spit out. He almost continually had his mouth full of it, and so there must have been many occasions on which it entered his trachea. The dentist and the anaesthetic were naturally exonerated in this case.

Case 2.—On May 1 I made a necropsy on the body of an elderly woman. A tooth fragment was found in the middle of the right lower lobe of the lung. There was no surrounding abscess, but a diffuse acute pulmonary oedema was present, with blood-stained froth in the trachea and bronchi. This had presumably been caused by the irritation of the tooth, for the heart was normal. She had, however, a rather severe chronic nephritis. In this case the coroner also exonerated the dentist and anaesthetic—there had not been either. The patient had suffered with bad teeth for some years, and parts were frequently breaking off (this was learned after the necropsy). She had resolutely refused to go to a dentist because she was frightened. Her husband left her in apparently good health, and when he returned two hours later she was lying dead on the kitchen floor. The cause of her death was a mystery until the necropsy was made. The tooth fragment was not an embolus, of course; and these two cases show the ease with which foreign matter can enter the trachea in the complete absence of anaesthesia.

Summary

1. General anaesthesia by itself is of very little importance in the aetiology of post-operative lung complications.
2. Aspiration of foreign matter into the trachea and bronchi occurs with surprising ease and frequency.
3. Lung complications have been reduced by attention to the causes of embolism (operative trauma, mobility of the affected part, and sepsis) and great care in preventing the aspiration of foreign matter into the trachea.
4. It is probable that embolism and aspiration are both important causes of post-operative lung lesions and that neither alone can explain all cases.

I am indebted to the coroner for Derby, Captain T. H. Bishop, O.B.E., for permission to publish notes on the necropsies recorded, all of which were made on his instructions.

CHLOROMA

A CASE HISTORY AND POST-MORTEM FINDINGS

BY

ROBERT E. HORSFALL, M.D.

Honorary Assistant-Physician, Victoria Hospital, Blackpool

Chloroma is a disease of particular interest, not only on account of its rarity but also because of its somewhat dramatic clinical course and the fact that it is considered to occupy a position intermediate between the leukaemias on the one hand and neoplasms of the marrow on the other hand. The number of authenticated cases reported in medical literature is small. Roehm, Riker, and Olsen (1937) state that up to the end of 1936 they amounted to only 194, and this figure is probably accurate, since the majority of cases presenting such a severe clinical syndrome as is characteristic of chloroma would, at some phase of the disease, be under hospital supervision and the diagnosis recorded. All these cases proved fatal with the exception of two, in which recovery is said to have occurred following operative removal of the primary tumour.

The aetiology remains obscure. There is a tumour-like hyperplasia, probably of the leucocyte parent cells, occurring primarily in the red marrow. Authorities differ as to whether the tumour cells should be considered myelocytic or lymphocytic: most cases appear to belong to the former category. In the present case the cells in the marrow and substernal tumour showed the presence of oxidase granules when stained by the Goodpasture technique, but they also showed the presence of a dense nuclear membrane which is not typical of the myeloblast. Roehm, Riker, and Olsen report a case in which the cells were too primitive to be labelled either myelocytic or lymphocytic.

Case Record

A girl aged 17, a laundress, was admitted to hospital on September 11, 1937, suffering from general weakness and protrusion of the left eyeball. Ten weeks previously she had had an attack of vomiting lasting three days and pains of neuralgic type in the left side of the face. She was becoming pallid, was easily tired, and developed diplopia.

Clinical Examination.—The patient was grossly anaemic but well nourished, with no jaundice or oedema; the left eyeball showed well-marked exophthalmos, being also dislocated downwards and outwards. The temperature was 100.5° F. The heart rate averaged 115 to 125; the apex beat was displaced half an inch to the left; and the first sound was reduplicated and accompanied by a short mitral bruit. Examination of the lungs revealed no anomaly except unduly harsh breath sounds and scattered rhonchi; there were no moist sounds and no signs of pleural effusion. The abdomen was normal, neither liver nor spleen being palpable. The nervous system was normal, but the ocular fundi showed bilateral papilloedema, scattered haemorrhages, and occasional patches of exudate. Palpation of the left supra-orbital margin revealed a moderately hard mass on the nasal side. Pressure along the sternum showed a positive Craver's sign—that is, tenderness at the level of the fifth costal cartilage. There was some deafness on both sides, but this was of middle-ear type.

Special Investigations.—The first blood count gave the following figures: haemoglobin, 25 per cent.; red cells, 1,080,000 per c.mm.; colour index, 1.3; white cells, 60,000, containing 43 per cent. myelocytes and 9 per cent. myeloblasts. Later counts showed that the white cells remained

My thanks are due to Dr. M. O. Abdine, ear and nose surgeon to the hospital, for giving me the clinical history of the case.

Alexandria.

Pathologist, Government Hospital.

Abnormality of Ribs

(WITH SPECIAL PLATE)

The following case possesses items of interest.

A girl aged 14 months was brought to this hospital, the mother saying she thought "that the right shoulder was a different shape from the other." On examination it was seen that the left shoulder was normal and the right appeared to be more square. There was a bony lump in the supraclavicular fossa, rather towards the posterior margin. An x-ray film disclosed absence of the second rib on the right side. The antero-posterior view (see Plate) shows that the ribs on that side are definitely thinner and less calcareous than those on the opposite side; they also show a concavity upwards instead of a convexity downwards.

I am indebted to Mr. G. Richardson for permission to report on this case.

W. A. BELLAMY, M.R.C.S., L.R.C.P.,
Sydenham, S.E. Assistant Radiologist, South-Eastern
Hospital for Children.

Hyperparathyroidism

(WITH SPECIAL PLATE)

The following case of hyperparathyroidism with generalized osteitis fibrosa may be considered worth recording.

CASE RECORD

A married woman, aged 40, complained of pains of a rheumatic character for the past four years, during the last two of which she had been treated for "rheumatism." At first the pain had not been severe and she could get about, but for two years she had been increasingly incapacitated by progressive weakness. During the past month she had noticed pain in the right arm and the left knee, and was radiographed. The skiagram showed some general decalcification of the bones and a cyst in the neck of the right scapula. Further radiographs revealed cysts in the os innominatum.

On examination the heart, lungs, and alimentary system were normal, and there was no urinary frequency. The patient, who was nulliparous, had been in good health up to four years ago, and her appetite had also been good. She always seemed to be drinking, but thought she had no frequency. Skeletal examination revealed a swelling in the upper part of the right arm, which was tender. The knees were also tender. The blood calcium was 15.9 mg. per 100 c.cm. X rays disclosed general decalcification of the bones: the right scapula, right os innominatum, left tibia at the upper end, right femur, upper end of right humerus, and right radius all contained areas of erosion. A uroselectan examination of the kidney showed a normal pelvis. No stones were present.

The patient was admitted to the Sheffield Royal Infirmary on November 17, 1936. An aspiration biopsy of the right humerus was performed by Dr. F. Ellis, and revealed an osteoclastoma. The diagnosis of hyperparathyroidism was confirmed, with generalized osteitis fibrosa. Further chemical examinations on December 12 showed the serum calcium to be 15.5 mg. and blood phosphorus 1.3 mg. per 100 c.cm. A spontaneous fracture of the upper end of the shaft of the right humerus occurred soon after admission.

Operation.—On December 20, 1936, under gas-and-oxygen intratracheal anaesthesia with rectal paraldehyde, I explored the thyroid gland and its surrounding structures. After considerable palpation and dissection a nodule about the size of a large marrowfat pea was discovered at the lower pole of the left lobe of the thyroid gland. It was lying apart from

the capsule but fixed to the thyroid lobe. On dissecting it off it ruptured, and was seen to be slightly cystic. Being rather disappointed with the findings, further search was made, and behind the first nodule another was found, about the same size but firmer in consistency. It, too, was dissected out and removed. The colour did not differ from that of the thyroid tissue. Search at the lower pole on the right side also revealed a body very much like that of the second; this, too, was removed, and all were sent for section. The pathological report stated that section of the nodules showed two of them to be typical parathyroid adenomas.

Recovery from the operation was good, but two days later a feeling of "pins and needles" developed in the fingers of both hands and spread all over the body. Typical carpal spasms associated with tetany developed, and some facial twitching occurred. There were no urinary symptoms. Ten c.cm. of calcium gluconate were given twice daily with 1 c.cm. of parathormone. The spasms and other symptoms subsided rapidly, and there were none ten days after the operation. The blood-serum calcium on December 29 was 8.2 mg. per 100 c.cm., and on January 7 10.9 mg.

Since operation steady progress has been made. All pain has disappeared. The patient can walk two miles now without fatigue. Her weight has increased considerably and she no longer feels tired. The bones have regained their calcium and the areas of rarefaction have disappeared. The fracture in the right humerus united with a slight deformity.

I am indebted to Dr. L. C. D. Hermitte for cutting the sections and for the photomicrographs, and to the radiological staff of the Royal Infirmary for the x-ray films.

A. W. FAWCETT, F.R.C.S.,
Honorary Assistant Surgeon,
Royal Infirmary.

Sheffield.

Tumour of Vocal Cord following Nasal Endotracheal Anaesthesia

As not many cases of laryngeal complications have been reported after intratracheal intubation the following may be of interest.

CLINICAL HISTORY

A married woman, aged 49, was admitted to the London Jewish Hospital on April 19, 1937, while I was house-surgeon, with chronic cholecystitis, for which cholecystectomy was performed on April 22. The operation took fifty-five minutes, and was performed under nitrous oxide-oxygen-ether anaesthesia through a medium-sized Magill's tube, inserted by the "blind" nasal route after repeated attempts. Except for some slight chest pain about three weeks after operation, which cleared up in a day or so, the patient made an uneventful recovery, and she was discharged on May 23.

On June 30, 1937, she attended the out-patient department with a complaint that she felt something moving up and down in her throat, especially on talking; that sometimes she was unable to talk, that occasionally she found herself talking in a high-pitched voice; and that once or twice she had "lost her voice" for a short time. All these symptoms were of nine to ten weeks' duration, and she had had no throat trouble of any kind previous to the operation.

On laryngoscopic examination by Mr. H. Kisch a small tumour was seen at the base of the right vocal cord. The major portion of this growth was removed on July 7, under intravenous pentothal anaesthesia. On the 14th the remaining small portion was found to have shrunk considerably and not to necessitate removal, and she was discharged on the 15th. Two months later there was no sign of the tumour, and since then she has had no throat trouble.

PATHOLOGICAL REPORT

The pathological report was as follows: "Polypus granuloma of unspecified nature from vocal cord, composed of fibrous tissue and numerous capillaries lined with larger endothelial cells; infiltrated with lymphocytes and plasma cells, and, superficially, polynuclear neutrophils covered with fibrin."

6. *Adrenal*.—Normal except for a few "chloroma" cells visible in capillaries of the connective-tissue capsule.

Kidney.—The naked-eye view of a section of kidney is distinctive because of prominent dark superficial areas. These are deposits of "chloroma" cells embedding tubules and glomeruli.

7. *Pancreas*.—The interlobular and interacinar stroma is almost wholly "chloroma" cells.

8. *Appendix*.—"Chloroma" cells constitute the interglandular stroma of the mucous membrane and the submucosa. Normal lymph follicles are preserved.

9. *Ovary*.—Converted into a solid "leukaemic" tumour; thickly scattered are aggregations of brown-yellow pigment, both coarsely granular and homogeneous. Normal ovarian stroma is inconspicuous. The interstices of the vascular pedicle are thickly infiltrated by "chloroma" cells.

10. *Mesenteric Gland*.—8 by 10 mm. Preservation of normal peripheral ring of follicles. Central pulp densely infiltrated by "chloroma" cells.

11. *Abdominal Gland*.—Enlarged, 25 by 15 by 10 mm. Contains active tuberculosis. Peripheral lymph nodes preserved, but the pulp, vascular pedicle, and external connective-tissue bed are solid leukaemic tumour.

12. *Femur Marrow*.—Paraffin section stained with haemalum and eosin. The main feature is dense cellularity, with very few fat spaces and an absence of the design of normal marrow. The predominant cell is distinctive, 12 to 20 microns, with large nucleus, mostly round, many slightly curved, some more curved or bilobed. The nuclear membrane is thick and prominent; some nuclei have dense large granules of chromatin, many are pale and vesicular; one, two, or three pink nucleoli are frequent. The cytoplasm is faintly basophil, and non-granular. Primitive erythrocytes are very scanty. Normal eosinophil and neutrophil granular cells, both primitive and mature, are moderately plentiful, but typical normal lymphocytes are absent. A few granular aggregations of golden pigment are present outside cells. A fresh film of marrow, stained for oxidase by the Goodpasture technique, shows that most of the large mononuclear cells give a marked positive reaction.

In the visceral deposits there is marked compression and distortion of the infiltrating cells by tight packing. Mitoses are frequent among the "chloroma" cells. Coarsely granular eosinophil leucocytes are present in most of the leukaemic deposits.

Discussion

In such a case as this there appears to be an uncontrolled stimulation to undisciplined multiplication of the myeloblasts or their parent cells. Whether such stimulation is due to some unknown infection or is a primary malignant change in the myeloblastic tissues remains in doubt.

The histological findings indicate, as one would expect from the clinical course, that chloroma is a much less benign disease than leukaemia. In the latter condition the tissues are infiltrated by the specific cells in a manner which may be described as a peaceful colonization; in chloroma, on the other hand, the tissues are invaded by an aggressive militant force with malignant potentialities, as shown by the frequent findings of active mitosis and the formation of tumour masses. The periosteum appears to be the most vulnerable part of the defence line, for here the attacking force makes most progress with the development of neoplasms.

I wish to express my thanks to Dr. W. Hayes, Dr. A. St. Clair Robertson, and Dr. F. B. Smith of Preston for their kind collaboration in this case.

Clinical Memoranda

A Case of Chloroma

(WITH SPECIAL PLATE)

This case of chloroma is recorded on account of the rarity of the condition.

CASE REPORT

History.—A boy, aged 6 years, was admitted to hospital on September 6, 1937, with marked double exophthalmos. He had complained of headache for the last month, previous to which he was in perfect health. Twenty days before admission the parents noticed protrusion of both eyes, which gradually increased until it became very marked. They also noticed that the boy's vision had not failed. On examination the most striking thing observed was the extreme double exophthalmos with oedema of the conjunctiva and a left corneal ulcer due to lagophthalmos. The patient was also greatly emaciated. The skull was big in proportion to the body, and a fairly large swelling at the right angle of the lower jaw and a smaller one at the left angle were present. There were greatly dilated veins over the scalp and forehead. The lymph glands of the neck were somewhat enlarged and discrete, but there was no enlargement of the axillary or inguinal glands. The circulatory and respiratory organs did not show any abnormality. The liver was three fingerbreadths below the costal margin, and the spleen was fairly big, reaching to half-way between the costal margin and the umbilicus. The temperature was 37° C. and the pulse rapid, and the patient's condition was unsatisfactory. There was epistaxis and left facial paralysis. The patient's four brothers are in perfect health. The case was diagnosed as "? thrombosis of cavernous sinus, ? intracranial tumour," and the skull was x-rayed, the radiological report being "increased intracranial pressure causing wide separation of sutures due to a general condition and, less likely, to localized tumour formation." No investigations, not even a blood count, could be made, as the patient died twenty-four hours after admission to hospital.

Pathological Findings.—On post-mortem examination the most striking things observed were the marked emaciation, the exophthalmos, and the enlargement of the skull out of all proportion. On opening the body the masses at the angles of the jaw were found to be soft, resembling sarcomatous tissue and being green in colour. The lungs and heart did not show any abnormality. The stomach contained a large amount of blood, evidently swallowed from the epistaxis the patient had had before death. The alimentary tract did not reveal any lesion. The liver was enlarged, and the most peculiar thing about it was the presence of green infiltrations along the portal tracts. The spleen was five or six times the usual size and was deeply congested. As to the urinary system, there were greenish infiltrations scattered in the cortex of both kidneys, but the genital and endocrine organs did not show any abnormality. The lymph glands of the neck, mediastinum, and mesentery were enlarged and discrete, with the same greenish coloration. On examining the skull and its contents thin deposits of the green material were seen underneath the temporal muscles and along the sutures, which were separated. The dura mater was found to be somewhat adherent to the interior of the skull, and subdural masses, broad and flat, were scattered all over the internal surface of the dura, only small areas of which were free (see Plate). All these masses were somewhat soft and of a green colour; they did not invade the brain, which did not show any lesion. The orbits were packed with this green material, causing the marked exophthalmos. On cutting into the petrous portions of the temporal bones the same material was also found, and this explains the left facial paralysis. The bone marrow revealed the same greenish coloration, which on exposure gradually faded into grey. Microscopical examination of the dural tumours showed the chloroma to be of the large lymphoid-cell type. These cells were infiltrating the liver along the portal tracts, the cortex of both kidneys, the lymphatic glands, the splenic pulp, and the bone marrow.

benign adenopathies such as Schaumann's disease, though these subjects have important practical bearings, and where can they be discussed better than in a textbook of haematology? Section 7 deals with miscellaneous conditions, and includes a good account of malaria. Section 8, on haematological technique, contains much useful information, but might have been better adapted to the needs of the text. The May-Grünwald-Giemsa staining method is not described, though it is recommended on page 407, whilst the Gordon test for Hodgkin's disease is given in full, though the text omits even the barest account of Hodgkin's disease.

All this is not to deny that the book gives much useful and readable information about important aspects of haematology, but merely suggests that it does not give sixty-five shillings' worth. To write a good textbook of haematology needs almost as unique qualities as to draw the sword Excalibur or the bow of Ulysses—much clinical work with patients, much experience of clinical pathology and morbid anatomy, much reading of publications in very different fields—and we still await the man who will combine these qualities with the patience to write a book.

A HANDBOOK OF MALARIA

Malaria: A Handbook of Treatment, Parasitology, and Prevention. By Bernard Nocht, M.D., and Martin Mayer, M.D. With a foreword by Sir Rickard Christophers, C.I.E., F.R.S. (Pp. 196; 25 figures, 2 coloured plates. 10s. 6d.) London: John Bale Medical Publications, 1937.

Professors Nocht and Mayer, as previously noted in this *Journal* when reviewing the German edition, have performed a most useful task in bringing out, in the form of a small handbook, a short modern account of malaria. The appearance now of an English edition of their work will still further add to its usefulness. The English translation is a small, handy, attractively printed volume, with a foreword by Sir Rickard Christophers. The account given is complete and up to date, and the book forms a ready means of reference to the most recent ideas on diagnosis, treatment, and prophylaxis, otherwise only to be found scattered through the extensive literature of the subject. It is especially up to date in the amount of information given regarding the new anti-malarial synthetic compounds such as atefrin and plasmoquine and their use in treatment and prophylaxis, as well as in the very full and detailed discussion on the dosage, modes of administration, and properties of quinine. After a brief reference to the history of malaria discovery, distribution, and statistics, an account is given of the clinical picture in malaria, including the characters of the attack by different forms of the parasite, pernicious manifestations, features of the disease in children, and the subsequent course and effects of the disease. Following this is an important chapter on treatment, dealing fully with the drugs used and their methods of administration. Next come short sections on such subjects as pathological changes in malaria, useful biochemical tests, induced malaria, immunity, serological reactions, and ape malaria. An adequate account is given of the technique of preparing and examining blood films and of the characters of the different parasites. There is a chapter on blackwater fever, and, finally, a short survey of the development of the parasite in the mosquito host and a very brief summary of preventive measures against malaria.

In the nomenclature of the types of parasite and forms of malaria the English edition has, rightly in the reviewer's opinion, followed the usual English rather than the German custom. Thus the parasite of malignant tertian

is referred to by the now almost universally accepted name among English and American writers of *Plasmodium falciparum*, and not *P. immaculatum*, as commonly employed by German writers and as given in the German text. The term "malaria tropica" has been replaced, as is usual among English writers, by "malignant tertian." Otherwise the translation follows the German text closely. While the book fulfils admirably the purpose for which it was, as the authors state, originally written—namely, for the use of the postgraduate student and medical man—it will also be of much service to the expert as a work of reference.

PICTORIAL AIDS TO DISSECTION

Illustrations of Regional Anatomy. By E. B. Jamieson, M.D. Five volumes. Second edition. (211 plates. 32s. 6d., postage 9d.) Edinburgh: E. and S. Livingstone, 1937.

The second edition of Dr. Jamieson's *Illustrations of Regional Anatomy*, Sections I to V, with the addition of Sections VI and VII, of the lower limbs, represents the complete series of this excellent pictorial aid to the student's work in the dissecting room and his study of the descriptive textbooks of human anatomy. Many new coloured blocks have been prepared for this edition, and some of the plates have been enlarged. The addition of colour is especially helpful in the distinction of certain of the nerve tracts of the brain, such as the superior and inferior longitudinal fasciculi, the cingulum and tapetum, the limits of which are not readily distinguishable in actual specimens. Also the clear, unabbreviated labelling of the illustrations is of great value at the present time, when so much has to be learnt in a very limited period of the student's curriculum. Moreover, the importance of a visual concept of the structural relations of parts being readily grasped and retained in the memory is a practical consideration which can hardly be overestimated.

Few criticisms are necessary in a work of such general good quality. From the artistic standpoint, however, some of the hollow viscera appear too rigid and too solid. Also, in Plate IV, the pharyngo-tympanic tube on the right side appears to slope forwards from the pharynx instead of backwards and laterally. That a demand for a second edition should have occurred so soon after the publication of the first is ample evidence of the sterling merit and usefulness of the work, and we can confidently recommend the "illustrations" as a reliable aid to junior and advanced students of human anatomy.

ELEMENTS OF PATHOLOGY AS APPLIED TO MEDICINE

An Introduction to Medical Science. By William Boyd, M.D., M.R.C.P.Ed., F.R.C.P.Lond. (Pp. 307; 108 figures. 16s. net.) London: Henry Kimpton, 1937.

Professor William Boyd, whose books on medical and surgical pathology have been so well received by students and teachers, has set out in his *Introduction to Medical Science* the elements of pathology as applied to medicine, and hopes that it will be found useful to medical students in the intermediate years of their course, to nurses, and to hospital technicians. He limits his subject-matter to an introduction, but has succeeded in his object of showing that the closest relationship exists between the pathological changes or lesions in the organs and the symptoms from which the patient suffers. The book follows the usual lines, the general principles of pathology being discussed under the headings of the causes of disease, bacterial and animal parasites, the phenomena of inflam-

COMMENT

In view of the fact that (1) the patient had had no throat symptoms of any kind previous to operation and (2) injury to the vocal cords is a definite and recognized, though comparatively uncommon, complication of nasal intubation, one is justified in assuming the above to be a case of complication of endotracheal anaesthesia.

I wish to thank Mr. S. I. Levy, senior surgeon, London Jewish Hospital, and Mr. H. Kisch, senior surgeon, ear, nose, and throat department, London Jewish Hospital, for their permission to publish this case.

MICHAEL COHEN, M.B., B.Ch.,
Resident Anaesthetist and Emergency
Officer, Addenbrooke's Hospital.

Cambridge.

Unusual Case of Rupture of Internal Semilunar Cartilage

The following case seems worth recording on account of two uncommon features: (1) the fact that the violence which caused the lesion was of a very unusual character, and (2) the complete absence of swelling of the knee-joint at the time of the accident and after.

CASE REPORT

The patient was a quarryman, aged 29. He stated that about the middle of August last he was struck on the inner side of his right knee by a piece of heavy stone the size of a cricket-ball. He received the blow while in a sitting posture, with the right knee flexed and the foot tucked under the left leg, which was fully extended. There seems to have been no acute pain at the time of the injury, and he not only went on working that day but continued to work for two months. He noticed, however, that something seemed to move in the joint and prevent complete extension, but he found that by alternately flexing and extending the knee and rubbing the inner surface free movement returned. Then at the end of October the knee "let him down" and his usual manœuvres failed.

He consulted me on November 1, when I obtained the above history, but close questioning then and subsequently failed to elicit any description of an injury corresponding to a twist or a wrench. On examination the knee looked quite normal; there was no obvious swelling of the joint, and this was confirmed by mensuration. The man said that at no time had he noticed any swelling. Over the site of the anterior half of the internal semilunar cartilage there was a point of marked tenderness. Extension of the joint was all but complete, and attempts to make it complete caused him to wince; flexion was quite free.

Conservative treatment was undertaken, but after ten days it was found that there was no improvement. He was then seen by a surgeon, and as x-ray examination proved negative it was decided to explore the knee. On November 30, the joint was opened through a curved incision, and the synovial membrane was seen to be acutely inflamed, though there was very little synovial fluid. The internal semilunar cartilage was observed to be split longitudinally, and the inner portion lay in the centre of the joint—the well-known bucket-handle tear. As much as possible of the cartilage was removed.

Healing took place without incident, and there was never any effusion into the joint. On the fourth day the pillow on which the knee was supported was taken away and extension was found to be complete and painless. Movement of the limb in bed was encouraged, and in less than a week later the full range of flexion was obtained. The patient was allowed out of bed on the eleventh day and walked without discomfort on the twelfth. He is now walking well, and his only disability is some difficulty in climbing stairs.

My thanks are due to Professor Graham Simpson, who saw the man and performed the operation, for his encouragement to me to publish these notes and for his co-operation in preparing them.

Bakewell.

HUGH G. WATSON, M.B., Ch.B.

Reviews

HAEMATOLOGY

Diseases of the Blood and Atlas of Hematology. With Clinical and Hematologic Descriptions of the Blood Diseases, including a Section on Technic and Terminology. By Roy R. Kracke, M.D., and Hortense Elton Garver, M.S. (Pp. 532; 44 coloured plates; 17 figures. 65s. net.) Philadelphia, London, Montreal: J. B. Lippincott Company. 1937.

At its published price the combined textbook of *Diseases of the Blood and Atlas of Hematology*, written by Dr. R. R. Kracke and drawn by Miss H. E. Garver, must be the most expensive book on blood diseases in the English language, and one eagerly turns over its pages to discover how much the author and the publishers have provided in return. The book is beautifully printed on a large page and is surprisingly light in weight. It contains over 500 pages, sixteen figures, and forty-four coloured plates. For the two last, curiously enough, no table or index is provided, and the index to the text is defective—for example, the reviewer looked in vain for osteosclerotic anaemia or leuco-erythroblastic anaemia and myelomatosis or Kahler's disease, though both subjects are mentioned in the text. The illustrations are well chosen and well reproduced, but while some of them are good, on the whole the artistry, and especially the representation of nuclear detail, fall below the standard of Continental textbooks. Compare, for example, Plate XI, nucleated erythrocytes, with Plate I in the 1923 edition of Naegeli's *Blood Diseases*.

Sections 1, 2, and 3 deal with terminology, morphology, and physiology of the blood cells. Dr. Kracke makes a strong case against the confusion and illogicality of current haematological terms, and pleads for a system which would prevent the introduction of contradictory words such as agranulocytosis. Unfortunately Dr. Kracke has been unable to avoid the pitfalls which beset attempts to reform terminology, and though he has not got so deeply bogged as Osgood some of his suggestions are hybrids, such as acidocyte for eosinophil polymorphonuclear and fragilocyte for the fragile cell of acholuric jaundice, and needless discords such as baso-erythrocyte and polychromatocyte. Scientific terminology cannot be reformed or standardized by a single individual, as is shown by the confusing efforts of Osgood and Kracke, or by a committee of a single nation, as is shown by the recent *faux pas* of the Council on Pharmacy and Chemistry of the American Medical Association. The time is ripe for an international co-operative attack on haematological nomenclature.

Sections 4, 5, and 6 deal with anaemias, leukaemias, and haemorrhagic diseases, which are clearly and simply described, though the note of personal experience is often lacking. Statements from the literature which most haematologists would disbelieve, such as that on the value of treating polycythaemia by gastric drainage or lavage, are given the same weight as the confirmed evidence of good authorities. Tropical nutritional anaemia is not mentioned (is that because haematologists in the United States of America have never distinguished it from sprue and pellagra?), and the account of leuco-erythroblastic anaemia is too meagre. Morbid anatomy and histology are almost entirely omitted. Splenic anaemia has some fifteen lines only under the anaemias of childhood. There is no discussion of Hodgkin's disease and related lymphoblastomatous conditions, or of their separation from more

graphy and some alterations in pathological nomenclature found necessary to bring descriptions of certain conditions into line with current opinion regarding their nature of origin—for example, osteoclastoma for the old myeloma. In the section on thyroid enlargements reference might have been made to the fact that a goitre displaces the common carotid artery outwards and backwards, as this is a diagnostic feature which has proved of value in certain cases. Twenty-two plates reproducing radiographs add to the value of the work: thus, for example, the x-ray appearances of the bismuth "swallow" in achalasia of the cardia and in oesophageal cancer may readily be compared and contrasted.

In the work entitled *Sex, Custom and Psychopathology* (London: George Routledge, 21s.), which is an ethnological and psychiatric study of the South African native, and particularly of the Tembu tribe, Dr. B. J. F. LAUBSCHER, senior psychiatrist to the Union Mental Service, gives a detailed account of the social practices, beliefs, and customs, and their influence on psychopathology in a primitive culture. The author's information was obtained from the hospital staff in the native wards, native doctors and diviners, the heads of kraals, elders and councillors, chiefs, etc., and the magistrates and native commissioners. In addition to a full description of the natives' folk lore, in which phallic worship plays a prominent part, an elaborate account is given of the initiation ceremonies which mark the transition from childhood to manhood or womanhood and form the most important epoch in the life of the native living in the kraal; the conception of mental disorder held by the native, which is closely connected with his environment and influenced by the customs and beliefs underlying witchcraft and magic; and the incidence of sexual offences, suicides and homicides among the natives. The text is interspersed with photographs of the natives and their ceremonies, and various types of mental disease. This vast collection of original research is a valuable contribution to anthropological and psychiatric literature.

Many of our readers will like to see and to possess a little booklet entitled *An Austin Twelve on the Frontier*. It is by Dr. E. GERTRUDE STUART, formerly in charge of the Church of England Zenana Missionary Society Hospital at Quetta. It consists of some forty pages only of actual text, but it contains also a considerable number of excellent photographic illustrations and is so well written as to present a very vivid and most interesting picture of medical missionary work on the North-West Indian border. After a few graphic pages on "The Frontier and its People" and on "The Building up of a Medical Mission," the narrative takes an autobiographical form, being put into the words of an old Austin car which has seen and done remarkably good service in a great cause. This scheme of presentation is carried out more effectively than such a method generally is. The medical and missionary work at the Good Shepherd Hospital and in the surrounding villages, the happenings of the great earthquake, the saving of lives and of property, and the heroic attentions to the sick and the injured are well described and indicated, and the booklet as a whole constitutes a most effective appeal for interest in, and practical help for, the work of the society under whose auspices it is issued at the price of 6d.

Protoformotherapy in Treatment and Prevention: Fifteen Years of Research on New Scientific Bases of Therapeutics, by Dr. N. E. ISCHLONDSKY of Paris (London: Kimpton, 21s.), contains an account of three lectures delivered by the author in Cairo under the title, "The Internal Secretion of the Embryonic Tissues, its Biological Significance and its Importance in Practical Medicine." He claims that "protoformative ineret," which appears to be some form of extract of embryonic tissue, is a cure for very many forms of disease.

De l'Influence de Divers Cations sur le Croît Microbien, by Dr. LUCIEN NEIPP (Paris: Masson, 90 fr.) is a monograph of which the greater part is devoted to a summary of researches which the author has carried out in this subject. The observation that the presence of minute traces of metals in some cases favoured the growth of micro-organisms promoted the popularity of the Arndt-Schulz' hypothesis, which states that toxic agents in minute doses produce a favourable action. Dr. Neipp found that salts of lanthanum, cerium, lead, and mercury when present in minute concentrations did cause augmentation of bacterial growth, but, curiously enough, no such effect was observed in the case of silver. He examined also the influence of metals on the surface electric charge of bacteria, but concluded that the effects produced by metals could not be attributed to their producing changes in the surface potential. The monograph is fully illustrated with tables and graphs summarizing the author's experimental results.

Preparations and Appliances

A SUTURE NEEDLE

Mr. NÖLL E. WATERFIELD, F.R.C.S. (Great Bookham, Surrey), writes:

Messrs. Allen and Hanburys have made at my suggestion the suture needle shown in the illustration. It consists of a needle, straight or curved, hollow in its whole length. At the

end distal from the point there is a flattened disk by which the needle is held; this same hollowed end is slightly funnel-shaped.

The method of use is for the needle to be inserted through both edges of the cut; the suture is then threaded through the needle until the end projects, this being then held and the needle withdrawn.

The advantages are: (1) The painlessness with which a suture can be inserted, due to the fact that there is no drawing through the skin of two thicknesses of ligature and the needle at the same time, but only the puncture of the needle itself; this, to take the same size suture, is of much smaller calibre in comparison with the ordinary needle. (2) The ease of threading. The "eye" of this needle is much larger in proportion than that of the ordinary needle.

THREE NEW PREPARATIONS

Messrs. H. R. Napp, Ltd., 3, Clements Inn, Kingsway, W.C.2, have sent samples of the following three products which they are introducing:

"Carbomucil" is a granular preparation of activated charcoal with desiccated vegetable mucins. The makers claim that the granules will disintegrate in the bowel, and that absorbent action of the charcoal will be exerted there and will not be exhausted in the stomach. The preparation is recommended for conditions in which there is absorption of toxins from the intestinal tract.

"Immidiol" is a fluid which contains anthraquinone glucosides in a salicylic acid alcoholic solution. It is recommended as a gargle (half a teaspoonful in half a glass of water).

"Caapi" or anti-coryza tablets contain atropine sulphate, caffeine, phenacetin, and quinine. They are recommended for the treatment of acute coryza.

mation, immunity and allergy, the disturbances caused by changes in the blood flow, and a general idea of tumour formation and malignancy. The separate organs are then dealt with systematically. The illustrations are good and numerous—over one hundred to the three hundred pages of text; many are explanatory diagrams and others are excellent photographs of patients and pathological specimens. This part of the book, as it comes from a master hand, gives a very good summary of knowledge, linking up the physiology of the body with the changes occurring in the pathological state. It might be useful to students before taking up a larger textbook, but is too short and lacking in detail to be sufficient in studying for examinations. For nurses it may be too elaborate, but could be usefully adapted by the lecturer to nurses as the basis for their instruction, without their studying it themselves. It is in the author's intention, however, that nurses should read it during their training, as he has added some practical chapters at the end on the means of preventing disease and on the duties of the patient's nurse in collecting for laboratory examination and testing the various excreta and pathological material required.

THE CONTROL OF NOISE

Noise. By A. H. Davis, D.Sc. No. 6, Changing World Library. (Pp. 148; 20 figures. 2s. 6d. net.) London: Watts and Co. 1937.

The problem of noise and its prevention is approachable from the point of view of psychology and of physics. Dr. A. H. Davis, although his work lies in the Physics Department of the National Physical Laboratory, so that he may be supposed to be chiefly interested in the various physical expedients for reducing the noise nuisance, such as floating floors, baffle silencers, rubber insulators, and various upholstery, by no means neglects the psychological approach. It is open to question whether we live in a noisier age than our fathers, but it cannot be doubted that we are more sensitive to noise. Herbert Spencer's ear-stoppers and Thomas Carlyle's double windows suggest that the Victorians had something to put up with, even before the mechanical age got fairly started, but apart from such irascible spirits as those just named the people in general did not seem to mind it. The modern man passes through streets noisy with traffic, but he has learned not to hear it, and goes to an office noisy with typewriters or a factory with more clamorous machinery, to which he adjusts himself, and in the evening he bears with philosophic patience the gramophones or radio sets of his family or his neighbours. No doubt a great deal can be done by the normally healthy person to accommodate himself to a noisy environment. How largely the problem is a psychological one is suggested by the fact that many town dwellers who can sleep in rooms overlooking a trolley tram route are unaccountably distressed by a rural night, with its continual rustlings and patterings, croakings and chirrupings.

The effect of noise on the human organism still calls for study. That it induces fatigue can hardly be doubted, if only by reason of the increased effort to speak and to hear. It is said that listening to jazz music has the effect of slightly increasing the physical strength as represented by strength of grip—perhaps a convulsive movement of the hand as if to throw something at the players. The sense of smell and the normal ability to distinguish slight changes in colour are also said to be increased under the stimulus of noise, which suggests a fear reaction, rendering other senses more alert. In later chapters the author discusses the measurement, control, and elimination of noise. But

when all is said and done the best sound-absorber is good manners. The young gentlemen who bang their car doors at midnight and make a noisy get-away need to have it brought home to them that they are guilty of anti-social behaviour, and so do all the rest of us who cause unnecessary noises. It is a question of education, on the one hand, and, so far as concerns the noise which unavoidably accompanies industry and transport, it is a question of mechanical engineering to make it as little noticeable as possible.

BIBLIOTHECA MEDICA AMERICANA

Vol. I. *A Brief Rule to Guide the Common-People of New-England How to order Themselves and Theirs in the Small Pocks, or Measels.* By Thomas Thacher. First published in 1677/8, reprinted in 1702 and 1721-22. Foreword by Henry R. Viets, M.D. (Pp. 52. 7s. net.) Vol. II. *A Discourse upon the Institution of Medical Schools in America.* By John Morgan. Reprinted from the first edition, Philadelphia, 1765. Introduction by Abraham Flexner. (Pp. 63. 9s. net.) Vol. III. *Adaptation in Pathological Processes.* By William H. Welch, M.D., LL.D. Reprinted from Transactions of the Congress of American Physicians and Surgeons, 1897, vol. IV, pp. 284-310. Introduction by Dr. Simon Flexner. (Pp. 58. 7s. net.) Baltimore: The Johns Hopkins Press; London: Humphrey Milford.

These three little reprints form the first three volumes of the fourth series of the Bibliotheca Americana published by the Institute of the History of Medicine from the Johns Hopkins University at Baltimore. They show the interest which the medical profession in the United States is taking in the medical history of their own country under the guidance of Professor Henry E. Sigerist. Each volume is printed in facsimile type, is provided with a portrait, and is given an introduction.

Thomas Thacher published his *Brief Rule* in 1677/8, and Dr. Henry Viets has made the volume noteworthy by the very excellent life of the author which introduces this reprint.

John Morgan, who wrote on the *Institution of Medical Schools in America* in 1765, is introduced by Dr. Abraham Flexner. He was of Welsh ancestry, and late in life studied under the Hunters in London, and afterwards in Edinburgh, Paris, and Italy. He returned to Philadelphia, and became well known as the first professor of medicine in America. His pamphlet is well worthy of reproduction on account of his high ethical standard, and for his advocacy of a sound preliminary education for those who desired to practise medicine.

Professor W. H. Welch's *Adaptation in Pathological Processes* is introduced by Dr. Simon Flexner. The essay is good reading, although it was written in 1897. It shows the influence that Cohnheim and Weigert had exercised over a mind that was by nature thoughtful and acquisitive.

Notes on Books

An eighth edition of Pearce Gould's *Elements of Surgical Diagnosis* (Cassell, 10s. 6d.) has been published eight years after the seventh edition and just fifty-three years since the first appearance of this work, which was originally written by Sir Alfred Pearce Gould and is now edited by his son, Mr. ERIC PEARCE GOULD. The reputation of this little book is so well established, particularly among medical students, that only passing reference need be made to it. In common with Treves's *Surgical Anatomy* and one or two other small manuals, it may be described as a student's vade-mecum, and the bulge seen in his pocket is not infrequently caused by it. The new edition includes a reference to intravenous pye-

Minister of Health, or the Secretary of State for Scotland, for an Order making compulsory the efficient pasteurization of milk sold by retail in its area." In recent official publications, while an increased consumption of milk is advocated, the factor of safety from pathogenic micro-organisms has been stressed.

The Association is in complete agreement with the view that the physical well-being of the people would be enhanced by increased consumption of milk, but it is alarmed at the spectacle of a publicly financed campaign for more milk-drinking unless the milk is rendered safe by pasteurization, or at least made less liable to convey disease by tuberculin-testing of cattle and the elimination of the reactors from herds supplying milk for human consumption. The Government may propose, but Parliament disposes. Opposition to the policy outlined in the White Paper may still be strong enough to defeat it or to twist legislation into a worthless form. The motive behind the Association's campaign is not to undermine any reasonable confidence in the nation's milk supply but to help the Government in its well-designed proposals for securing that the supply generally merits confidence, by placing the facts before the public and their representatives. The milk producers and their representatives would be well advised to realize that a greater consumption of milk in this country is unlikely to be attained unless there is some guarantee of its safety, and that the mere cleanliness on which they tend to concentrate is not enough.

DRUG. ALLERGY

Sensitization to chemical compounds is a fascinating, if at times alarming, study. Alarming are the fatal allergic reactions in human beings which have followed the ingestion of even minute amounts of aspirin; fascinating are the varied animal experiments conducted during the past fifteen years to determine the precise manner in which these chemicals lead to anaphylactic responses. In order that the full significance of these reactions may be grasped a few of the facts concerning allergy to chemicals and drugs should be appreciated. We are not concerned here with reactions caused by drugs applied locally to, or in various occupations coming directly into contact with, the skin, but with drugs or chemicals usually inhaled, ingested, or injected. It is necessary to distinguish between the allergic reaction to the drug and the toxic action. In the latter case the symptoms are an exaggeration of the pharmacological action, and so vary from drug to drug; they may be produced

in all persons by an overdose. In another group of persons the ordinary pharmacopoeial dose of the drug, which should bring about only a normal physiological response, gives rise to similar toxic symptoms, and to these cases the term "drug intolerance" is applied. In cases of drug allergy even a fraction of the average dose of the drug will excite—only in certain persons—a train of symptoms never produced by the toxic action of the drug; they include fever, skin eruptions, asthma, and vasomotor rhinitis, and similar or identical clinical manifestations occur whatever the chemical nature of the drug. In fact it seems remarkable that an allergic reaction to such antipyretic drugs as antipyrine or quinine often includes hyperthermia. The same drug may cause a different grouping of the characteristic clinical symptoms in different allergic individuals, but it is always some of the same group of allergic symptoms that are produced by widely different drugs. It is usual for drug allergy to exist to only one substance or chemical group (for example, the phenyl group), and in this respect drugs differ from protein antigens in that in the latter the allergy is to the entire molecule, whereas in the former a certain element or chemical group is responsible. Variations may arise even in very closely related isomers of the same drug, allergic reactions following the use of the laevorotatory compounds while no allergy exists to the dextrorotatory isomers. Also, in allergy to a glandular product such as insulin the sensitiveness may exist to the protein of the animal from which the endocrine product was derived (for example, pig, ox, sheep), but in some cases it occurs with the pure hormone itself. Allergic reactions to drugs are quite common in persons allergic to ordinary protein substances, and the manifestation produced by the drug is usually the common condition from which the patient suffers. Skin tests with drugs are usually of little or no value except in cases of contact dermatitis. Many of the drugs are insoluble, and so intradermal tests are not possible. Negative reactions are often obtained in individuals with definite clinical sensitivity, while some drugs (for example, morphine and codeine) give prominent wheal reactions even in normal skins.

On the clinical side such facts concerning the natural drug allergies are well exemplified in a recent study undertaken by H. F. Buchstein and L. E. Prickman.¹ They have surveyed the literature concerning allergic reactions from aspirin and have reviewed sixty-two cases from the records of the Mayo Clinic. The following were the common characteristics. (a) In practically all cases there was

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY FEBRUARY 5 1938

THE ASSOCIATION'S MILK POLICY

It is not the desire of this *Journal* to criticize the views of other organs of the Press as to what the public should or should not be told, but the position revealed in an article in the *New Statesman and Nation* of January 22 calls for a statement of the British Medical Association's milk policy. Without committing itself to support of this policy the article expresses doubt as to the propriety of newspapers refusing the Association's advertisements urging that milk should be safe. The occurrence of milk-borne disease has been a matter of constant concern to successive generations of medical practitioners, and many family doctors consistently advise their patients to boil all milk before consumption. They deprecate especially the use of raw milk for the feeding of infants and young children, because it may contain tubercle bacilli and other pathogenic micro-organisms. Until recently, however, there was some division of opinion as to the form which a national programme should take. Some medical men thought, with the more enlightened agriculturists, that a planned policy for the eradication of disease in herds and the safeguarding of milk from contamination at the source or in transit was practicable and desirable. They knew that the measures which medical officers of health were able to take in farms and dairies were hampered by the inertia of their own councils and the imperfections of the law, but they watched with interest and sympathy the efforts of the Ministry of Food and, later, of the Ministry of Health to raise the standard of the milk business by a voluntary system of grading. Even those who were sceptical as to the prospect were unable to disregard the increasing importance attached to the quality of freshness in food, following the remarkable series of discoveries relating to vitamins since the first decade of this century. They recognized that the detriment to health from the heating of milk *might* be greater than the gain from reducing its liability to convey infection. So long as there was room for doubt on this point the Association refrained from expressing its corporate opinion.

Since the war wide experience of the feeding of infants of all social classes with dried, and therefore denatured, milk appropriately supplemented

by vitamins, and numerous feeding experiments both on human beings and lower animals, have proved beyond scientific doubt that heating does not, in practice, detract from the value of milk as a food. At the same time, pasteurizing plant and practice have reached a high level of efficiency, and the phosphatase test has furnished a reliable index of the proper application of the method to any volume of milk ostensibly pasteurized. Officers of local authorities have learned from Government publications and the terms of official Orders how to inspect the equipment and procedure of pasteurizing firms, and plant is obtainable at a reasonable cost for handling milk in relatively small bulk. Pasteurization on a wide scale has therefore become a practical proposition. On the other hand new knowledge of the prevalence in cattle of diseases like contagious abortion, and streptococcal and salmonella infections communicable to man has made it clear that elimination at the source is a far bigger problem than used to be thought.

With these facts before it the Council of the British Medical Association reported to the Annual Representative Meeting in 1935 that, in its opinion, "local authorities should be enabled, after a reasonable period of notice, to prohibit the sale in their areas of milk which is not from tubercle-free herds or has not been submitted to approved treatment to render it bacteriologically safe." The Council's report was approved. In 1936 it was felt that the milk question should be fully ventilated, and accordingly the Representative Body of the Association was asked to vote on a recommendation "that only milk complying with the conditions required for the designations 'Tuberculin Tested' or 'Pasteurized,' or preferably both, can safely be consumed without boiling." In moving the recommendation the Chairman of the Public Health Committee made a full statement on the milk position, in the light of modern knowledge. After discussion the recommendation was adopted with only one dissentient, and accordingly became the policy of the Association. A year later the Representative Body was informed that this resolution had been conveyed to the Ministry of Health, a further opportunity thus being offered for the expression of any contrary opinion. There was no opposition. This policy can therefore safely be assumed to express the considered and remarkably unanimous opinion of the members of the Association, which has therefore endeavoured to propagate it. The policy appears to have been endorsed by the Government itself, for as recently as last July, in a Command Paper entitled *Milk Policy*,¹ it announced its proposal "that, subject to certain conditions, any Local Authority shall be enabled to apply to the

¹ Cmd. 5533. H.M. Stationery Office, July, 1937. (2d.)

functions which civilization forces upon it. Lake, in his book on the foot, gives reasons to suppose that many deformities, such as hallux valgus, splay-foot, etc., are due as much to inherent tendencies in the foot as to the abuse of footwear. How otherwise can the numerous cases of these conditions which occur in patients who have never worn extreme types of footwear be explained? Lake concludes thus: "We can sum up man's footwear of to-day by saying that, if not quite ideal, it is at least a happy compromise with utility and as such cannot be subjected to much serious criticism. The same cannot be said, however, in the case of women's shoes, for here the manufacturer has been compelled to bow to the dictates of fashion." If this attitude is correct it would be rash to assume that much improvement would necessarily follow the universal adoption of "rational" footwear. Nor would it be wise, without much more investigation and unanimity of opinion, to dictate to the shoe manufacturer what constitutes the ideal shoe, lest it be a case of the blind leading the blind. The most altruistically inclined maker of rational footwear has to depend for guidance upon mere creeds which he sometimes mistakes for scientific knowledge. As a result there is on the market to-day footwear extolled because it throws the weight on to the outer border of the foot, or in another make on to the inner border of the foot, in another because it is rigid, and in another because it is flexible. Amidst such diversity of opinion it is dangerous to be dictatorial. There is a real risk of falling into an error, common enough, of attributing every trouble which arises to the operation of some external and preventable cause. This specious assumption is popular since the alternative suggestion that inherent tendencies may be responsible leads logically to some uncomfortable and unwelcome conclusions. There is obviously need for careful inquiry into the whole subject by a group of unbiased people representing various shades of opinion from both the medical and the manufacturing aspects. It may be recalled that Charles V found it necessary to forbid the wearing of *trop outrageuses poulaines*, and that in this country in the reign of Mary the width of the broad-toed shoe of Henry VIII was restricted by royal decree to six inches.

INFLUENZA VIRUS VACCINES

Active immunization against virus diseases is often believed to demand the administration of living virus, however attenuated. It has recently been pointed out by Bedson¹ that this belief can no longer be accepted; killed virus will immunize experimentally against several infections, such as herpes and psittacosis, and in practice as well as experimentally against distemper. There were therefore reasons for hoping that killed preparations of influenza virus would immunize. That they do so was proved experimentally, and attempts were made during last winter in this country by Andrewes and Wilson Smith to apply this method in the clinical field, unfortunately with inconclusive results. Meanwhile, investigators in the United States

have adopted the bolder plan of injecting suspensions of living virus intramuscularly for the purpose of immunization, since it appears that the administration even of fully active virus by this route is followed by no ill effects. An account has now appeared by Stokes, McGuinness, Langner, and Shaw² of two years' efforts on these lines. The subjects of the experiment were the inmates of five State Colonies—institutions which have more than once before proved a boon to the immunologist conducting a practical test on a large scale—and the treated individuals and controls were separated on an alphabetical basis, than which nothing could be more judicial. The preparation of virus used was a chick embryo culture, and no ill effects were caused by it. The results may be expressed briefly by saying that among individuals so treated the amount of febrile upper respiratory tract infection was significantly less than in controls; reckoned in numbers of such attacks the difference is less than when reckoned in total days of fever. It must therefore be concluded that this method of immunization does afford a substantial degree of protection. With more concentrated virus suspensions and perhaps more frequent administration the results might possibly be even better. Whether this method will ever be capable of general application is another matter. Taking the broadest possible view of the problem, it may well be asked whether epidemic infections of the air passages cannot better be attacked by some other means altogether, perhaps by mitigating the conditions in which they spread. These are air-borne infections which thrive as a rule only in winter, and it may prove in the end more feasible so to purify the air we breathe that their spread is prevented than to try to protect ourselves by inoculation against what, after all, are insanitary conditions.

BUMPER FRACTURES

Attempts to improve riding comfort and increased speed have led to a lowering of the height of the chassis of the modern motor car the world over. The chassis height, as measured from the level of the road, determines the position of the bumpers and the site at which fractures take place when the bumper comes into violent enough contact with the legs of a pedestrian. A fracture by direct violence is produced just below the knee, and the popliteal artery or its terminal branches may be damaged and gangrene of the foot result. F. G. Dyas and M. L. Goren of Chicago have lately emphasized the significance of these facts in a paper on bumper and fender fractures.³ Within six months four patients with gangrene following such fractures were seen in the Cook County Hospital, and these cases are becoming frequent in this country as well as the U.S.A. F. J. Cotton and Richard Berg⁴ introduced the term "bumper fracture" some eight years ago, and defined it as a crushing injury produced by abduction of the leg forcible enough to smash the external tuberosity of the tibia against the fulcrum of the

⁴ *Proc. roy. Soc. Med.*, 1937, 31, 59.

either a personal or a family history (or both) of allergic disorders, especially asthma. (b) The first onset of symptoms in a few cases followed the first known ingestion of the drug, but in most the drug had been taken many times before without ill effect. (c) The reaction is usually an exacerbation of the patient's allergic disease, quite rapid in onset, coming on within a few minutes to a few hours, and usually exceptionally severe, prolonged, and resistant to treatment with adrenaline. Many deaths have been recorded. Oedema appears as the characteristic pathological finding, whether of the lungs, face, larynx, or gastro-intestinal tract. (d) There was a high incidence of nasal polypi in patients extremely hypersensitive to aspirin. The moral of the study is that aspirin should be employed with caution in any allergic patient, especially if asthmatic, and that it should never be given to one who has nasal polypi. J. S. Davis and L. F. Frissell,² from a survey of the literature on amidopyrine and from their own experience, favour the view that *agranulocytosis* is an allergic reaction to amidopyrine. In skin tests with amidopyrine on fifty individuals the only positive reaction was obtained in a patient who was extremely sensitive to the drug. On the experimental side Landsteiner and his co-workers have studied the sensitization of animals with simple chemical compounds by intracutaneous or superficial administration. They had shown previously (1922, 1924, 1930) that artificially conjugated antigens could sensitize, their reactions being specific for the substance linked to the protein. In further experiments (1935, 1936), using benzoyl chloride and *p*-chlorobenzoyl chloride, they suggested that the sensitization effects induced were due to conjugated antigens formed *in vivo*, but they did not consider this very surprising, as both substances were easily decomposed by water and were highly reactive with proteins. In recent experiments³ they have employed picryl chloride (2:4:6 trinitrochlorobenzene) and 2:4 dinitrochlorobenzene; substances relatively stable as regards both their solubility in water and combination with serum proteins at serum alkalinity, and both known to cause allergic phenomena in human subjects, the former on intracutaneous administration and the latter in industrial workers handling it. Sensitization followed a series of intracutaneous injections, the presence of antibodies in the serum was shown by passive transfer, and shock resulted when the corresponding protein conjugate made by gently shaking horse or guinea-pig serum with the finely ground drug was given intravenously. These later experiments again suggest the combination of the simple chemical with

some substance of the animal body to form an antigenic conjugate. The protein conjugate theory would hardly seem to apply to natural drug allergies, for in ordinary cases the reaction occurs far too quickly to allow time for any protein union, such as with insoluble aspirin, but nevertheless Landsteiner's experiments are very convincing in the absence as yet of any worthy alternative theory.

DOES THE SHOE FIT?

Much attention has been devoted in the past few weeks in our correspondence columns, and subsequently in the lay press, to the question of the provision of "correct footwear." The Government industrial research organization also has been investigating the best type of footwear to suit various trades and occupations. To some the problem appears easy to solve. They believe that by the adoption of a shoe having a tight-fitting heel raised but slightly off the ground, a broad spatulate toe giving freedom of movement for the toes, and a straight inner border, all the many foot troubles of the present day (except, of course, those due to congenital lesions or acquired disease) might be abolished entirely. There is reason, however, to think that the problem is not quite as simple as this. It will be agreed that in modern civilized conditions some form of foot protection is needed and that such protection can only be adequately achieved by something more than a mere sandal—in other words, by a form of shoe having "uppers." If this is conceded it is obviously of the utmost importance that the means of protection should not in itself produce disability. Those who have implicit faith in Nature advocate shoes of the above type because they believe that in this way they are restricting the foot as little as possible in the carrying out of its natural functions, and that in these circumstances no disability can possibly arise. Unfortunately, under civilized conditions our feet have very unnatural functions to perform. A moment's thought will show that the adoption of level roads and pavements, etc., means that we use our feet only in a limited and stereotyped way, and that in consequence many of the movements of which they were previously capable are abandoned, while, within the limited range of movement now required, the strains, stresses, and wear and tear are increased excessively. Furthermore, the foot is a part of the body which is undergoing comparatively rapid evolutionary change, in which, therefore, variations in the proportions and strength of its components are both large and common. While in no way belittling the tragic effects of outrageous forms of footwear, we should be careful that all the facts have been assessed before we lay the blame for all foot troubles upon the manufacturer of boots and shoes: perhaps the adoption of an unnatural mode of life also has something to do with it. Indeed, a shoe having the purely negative virtues mentioned above may not in the long run be as advisable as one which lends some positive assistance and support to a structure which is grossly abused by the restricted

² *J. Lab. clin. Med.*, 1937, 23, 107.

³ *J. exp. Med.*, 1937, 66, 337.

biology and Pathology of the Queensland Health Department, gives an interesting description of this new so-called "Q" fever, and Drs. Burnet¹ and Freeman of Melbourne, the former well known for his researches on filterable viruses, contribute an account of the demonstration of the responsible organism in the tissues of inoculated mice. The disease has so far been met with chiefly in abattoir workers and dairy farmers. It is characterized by an acute onset and a fever that tends to fall fairly rapidly after one to two weeks, or more gradually after three or four weeks; convalescence is of variable length, and so far no fatal cases have been recorded. The outstanding symptom is headache, which is very severe and may resist treatment for some days; a rash is uncommon, but may occur in the second week. The blood usually shows a relative and an absolute lymphocytosis. Ordinary bacteriological examinations are negative. The differential diagnosis has to be made from influenza, Weil's disease, enteric fever, typhus, and seven-day fever. The definitive diagnosis is made by the inoculation of guinea-pigs with blood taken from the patient during the first fortnight of the disease, or less often with urine during the later stages and the early part of convalescence. The guinea-pig develops a febrile reaction of abrupt onset and decline, lasting four to six days, and subsequently is immune to re-inoculation. If the guinea-pig is killed during the fever, its liver is found to be highly infective for normal guinea-pigs and for mice. Mice, like guinea-pigs, develop a non-fatal disease. Examination of the mouse's spleen seven to ten days after inoculation reveals the presence of intracellular microcolonies of Rickettsia-like bodies staining purple with Giemsa; the virus is believed to be a new type of Rickettsia. The Weil-Felix reaction, it may be noted, is completely negative both in man and animals. The epidemiology of the disease is still obscure, but now that it is possible to make a laboratory diagnosis with considerable certainty it should not be long before the mode of infection and spread is known.

YELLOW BLACKBOARDS

Some six years ago, at the request of various interested bodies, the National Institute of Industrial Psychology began a series of investigations into working conditions in schools, utilizing the invaluable experience it had already gained in connexion with work in factories and offices. It started by examining the types of school buildings already in existence, and finally included such matters as a survey of sickness absences in various types of school and a study of the various systems of heating, ventilation, and lighting. The determination of the most suitable environmental conditions for children and teachers in the school became of increasing importance. In considering school equipment it was thought that no more fitting subject could be chosen than that familiar and somewhat formidable landmark in everybody's education—the school blackboard. Apparently, writing on a large piece of slate with a small piece of slate

was the earliest attempt at blackboard instruction, and in imitation of the teacher the children did likewise on miniature blackboards, or slates, with slate pencils. The blackboard evolved to become what we all know it to be, and the children's slate became extinct, to be succeeded by white paper written on by pen and pencil. While it was recognized that the strain felt by children in copying from the blackboard might be due in part to the repeated movements of the head and the eyes and to changes in accommodation and convergence, it was thought that it might also be due to copying from a black board on to white paper. The National Institute of Industrial Psychology has now published a report, by W. Douglas Seymour,¹ which threatens to put the blackboard along with the slate among other educational vestiges. In copying from a blackboard children have to move their eyes from a black surface with a reflection factor of 10 to 15 per cent. to a white surface with a reflection factor of 85 to 90 per cent. The object of the work done by the Institute was to discover whether a board with a far higher reflection factor than the blackboard would enable children to copy from it more quickly and with less strain. As a white board would be likely to cause glare a light yellow board was chosen for the experiments. Blue was chosen as the colour of the chalk. Two methods—a laboratory reaction-time test and class-room tests—were used. An instrument was devised to record on a moving tape the times taken by adults to read successively exposed short syllables presented first in white letters on a black board and then in dark blue letters on the yellow board. The results showed clearly that the words on the yellow board were read more rapidly than those on the black board, the average difference being 15.4 per cent. In the classroom experiments the speed of copying the usual white letters on a blackboard was compared with that of copying dark letters on a light board. The tests were carried out in four schools in Barking and Ealing. A test passage of 100 words was written on the board and the children were told to read it right through and then copy it on paper. Three different methods of trial were adopted, covering over 1,000 cases and under ordinary classroom conditions. The results pointed definitely in the same direction: the children were found to copy nearly 10 per cent. more in the same time from the yellow board than from the black board. This saving in time, it is suggested, represents a material reduction in strain. Further investigation is being made of the most suitable materials from which boards of the colour found best from the visual standpoint may be constructed.

On February 14 Sir Arthur Keith is giving a lecture at the Royal College of Surgeons on "The Prehistoric People of Mount Carmel," when he will be presented with a bronze bust of himself, subscribed for by a group of his friends, to commemorate his twenty-five years as Conservator of the Museum of the Royal College of Surgeons.

lateral condyle of the femur. The popliteal artery is most vulnerable in the lower part of its course where it is related to the popliteus muscle behind the head of the tibia. At this point, just below the origin of the lowest genicular branches of the main artery, the collateral circulation is poorest; hence damage at this site is likely to result in gangrene. In addition to the risk of indirect traumatic gangrene, bumper fractures are liable to produce much disability by depressing the outer tibial condyle and so interfering with normal movements at the knee-joint. Dyas and Goren describe a method of elevating the depressed condyle by means of a bone graft in cases which cannot be treated successfully by manipulation.

NEUTRONS FOR RADIOTHERAPY

Knowledge of the behaviour of neutrons has rapidly accumulated since their discovery by Chadwick less than six years ago. Physical methods of detection are probably not hindered by the smallness of the amount of matter or energy which may be dealt with, but biological research generally needs relatively strong sources of energy before any well-marked effects can be observed. The invention of the cyclotron by E. O. Lawrence¹ within two years of the discovery of the neutron was thus of the greatest importance to biological research. In this apparatus a beryllium target is bombarded with 5-million-volt deuterons (heavy hydrogen nuclei), and a beam of neutrons is produced comparable in power to the x-ray and gamma-ray beams used in radiotherapy. It will be remembered that whereas the absorption of x rays concerns mainly the electronic system of the atom, that of neutrons is restricted to the nucleus. Thus, with x rays, the heavier the element the greater is the absorption; but for neutrons, the laws of absorption of either corpuscular or quantum radiation do not apply. Their absorption depends rather upon the collision cross-sectional area of the nucleus, so that a high coefficient of neutron absorption is found for some elements of very low atomic number—for example, hydrogen, lithium, and boron. For x rays, gamma rays, or neutrons, however, the result of absorption is the production of ionization tracks in the tissues. It would therefore be expected that the biological effects of these various radiations would be essentially similar, though some differences might arise from different selective absorptions of the primary radiation or from the varying velocities of the ions produced. So far the biological effects of irradiation with neutrons have been observed to be similar to those produced by x or gamma rays. Thus animal lymphoid and haemopoietic tissues² have been found to be the most affected by neutrons, as they are by x rays; the lethal effect on *Drosophila* eggs, the retardation of the root-growth of wheat seedlings, and the inhibition of cell-division in fern spores³ have been produced by neutrons in the same way as by x rays; a transplantable mouse sarcoma⁴ has been destroyed *in vitro*; and skin

epitheliomata and recurrent nodules of mammary carcinoma⁵ have been made to disappear in the human subject. Though the biological effects of neutrons and x rays are thus similar, it does not necessarily follow that the mechanism of their production is identical. For accurate comparison measurement of dosage is essential. At the present time neutron dosage is conveniently expressed in roentgens, 1 r of neutrons being that dose which produces the same amount of ionization in the thimble chamber of a roentgen-dosimeter as would be produced by 1 r of x rays. It is then found that for equivalent doses in roentgens neutrons are more effective than x rays: for the *Drosophila* eggs they are 2.1 times more effective; for the wheat seedlings, 5 times; for the fern spores, 2.5 times; and for the lethal effect resulting from the whole-body irradiation of mice,⁶ neutrons are four times more effective than x rays. It would therefore appear that the relative susceptibility of various cells or tissues to neutrons may differ much from their relative susceptibility to x rays, though the general order of radiosensitivity of cells (as first expressed in the "law" of Bergonié and Tribondeau) may be the same for both types of radiation. There are thus at the present time two ways in which radiotherapy with neutrons may be advantageous: first by the exploitation of these relative susceptibilities; and, secondly, by increasing the absorption of neutrons locally by a local increase in the concentration of light elements such as boron. This latter is a possibility capable of much easier realization than that of increasing the local absorption of x rays by the injection of heavy metals. For the future, there emerges also the question whether sufficient quantities of artificially radio-active elements can be produced in the tissues to be of therapeutic importance. There is one further important deduction to be drawn from Lawrence and Tennant's paper. They point out that, since neutrons per equivalent roentgen are four times more effective than x rays as regards the lethal effect resulting from whole-body irradiation, the average daily dose to the personnel working with neutrons should not exceed one-fourth of the tolerance dose accepted for x rays. Even so, whether daily doses of this magnitude over a length of time will cause damage is not yet known.

"Q" FEVER

One of the most encouraging advances made in the field of medicine since the war has been the gradual extraction of a number of definite infectious diseases from the rubbish heap labelled Pyrexia of Unknown Origin. To the list of brucella, rickettsial, leptospiral, and filterable virus infections which have been identified by combined clinical and bacteriological investigation must now be added a new disease that has just lately been recognized in Australia.⁷ In a recent account Dr. Derrick,⁸ the Director of the Laboratory of Micro-

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

SALINE INFUSIONS

BY

HAMILTON BAILEY, F.R.C.S.

Rectal Saline Infusion

Rectal saline infusion has the advantage of simplicity; it requires neither special apparatus nor asepsis. A drachm of salt to a pint of water at a temperature of 115° F. is allowed to gravitate into the rectum through a funnel and tube connected to a catheter. The patient's hips are elevated, and the funnel is held at a height of two feet. The usual amount of infusion is half a pint every four hours.

The celebrated John B. Murphy of Chicago introduced continuous rectal saline infusion (proctoclysis), which was a distinct advance, especially in cases of peritonitis. Slow continuous delivery of the saline aided its absorption, and with less disturbance to a patient in a critical condition. Murphy emphasized that the height of the reservoir should not be more than one foot above the rectum (Fig. 1), that the delivery tube should be of comparatively wide calibre, and that his glass bulb with many perforations (Fig. 1, inset) should always be employed. *It is to be noted especially that in Murphy's apparatus there is no valve or dripper in the circuit; thus flatus can be expelled up the wide rubber tube into the reservoir.* These simple principles have not been fully appreciated, and need further diffusion among the medical and nursing professions.

FIG. 1.—Diagram embodying the essential principles of proctoclysis as laid down by Murphy. Inset: Murphy's glass cannula; the part to the right of the dotted line lies within the rectum.

Many consider that the administration of saline by the rectal route satisfies almost every requirement. I have heard it said that if a mariner with "water, water everywhere, but not a drop to drink" were equipped with a funnel and tube he could absorb enough sea-water via the rectal mucosa to avert death for days or even weeks. Whether or not this is true, a close observer soon realizes

that rectal saline, even when given by an experienced and painstaking nurse, is sometimes returned, particularly in cases where it is most needed. I am compelled to agree with Willard Bartlett of St. Louis that whoever wishes to adopt saline by the rectal route exclusively should first administer it a few times in person, and watch the results.

Summarizing, rectal saline is simple, safe, but slow and not satisfyingly certain.

Subcutaneous Saline Infusion

The apparatus for administering saline subcutaneously consists of two sharp-pointed aspirating needles which are attached to some form of infusion apparatus by a Y-shaped glass connexion. The subcutis beneath the breasts is usually chosen for the injection. The skin is sterilized and the sterile needles are inserted with the saline already flowing. They are kept in place with adhesive tape. The fluid should be at a temperature of about 112° F.; it cools considerably while passing through the tubes. The container is raised to a height of three feet, and the saline must gravitate at such a rate that there is no undue swelling of the subcutaneous tissues. It is often possible to give two or more pints of saline by this method without removing the needles.

This mode of administration of saline is inclined to be painful; it cannot be continued for more than a few hours; and the tendency is to replace it by the more certain method of continuous intravenous infusion, which can be administered without discomfort and with great precision.

Intravenous Infusion

Given in a massive single dose (a pint or more) intravenous infusion has many times saved life. True, saline and other isotonic solutions are but a poor substitute for

FIG. 2.—Funnel and tube in readiness for an intravenous infusion. Some fluid has been allowed to escape from the nozzle in order to be certain that there is no air in the tube.

whole blood, but occasions arise when urgency forbids the delay inseparable from blood transfusion. When a patient is collapsed his veins will be in a like condition, and it is necessary to insert a cannula into the vessel.

Technique.—Before the vein is exposed the funnel and tubes should be filled with the solution. To ensure the absence of air in the tube and nozzle some fluid is permitted to escape. As soon as air-locks and bubbles are eliminated the tube is clipped (Fig. 2). A rubber catheter

is placed round the arm. If the veins in front of the elbow are not visible the venous blood is milked upwards from the wrist. A folded towel is placed beneath the elbow to hyperextend the joint. If the patient is conscious a little local anaesthetic is injected into the sterilized skin over the vein. A short transverse incision is made through the skin, and the beak of a small haemostat is introduced into the wound and its jaws opened widely (Fig. 3). If this manœuvre is carried out once or twice the

FIG. 3.—A rapid and efficient method of displaying a subcutaneous vein through a small transverse cutaneous incision.

vein will be cleared from the subcutaneous tissues better than by painstaking dissection, and there is no fear of tearing even a delicate vein. Two catgut ligatures are passed beneath the vein; the lower is tied and the ends are caught in the haemostat. Using gentle traction on the latter, a small transverse nick is made in the vein wall. The anterior wall of the vein is held up (Fig. 4) until the nozzle (through which the saline is now running) is within the lumen; then the proximal ligature around the vein and the nozzle within it is tied. After the administration, as the last ounce of fluid is gravitating into the vein, the cannula is withdrawn and the ligature surrounding the vein is tied quickly. Two skin sutures are required to complete the operation.

FIG. 4.—A vein exposed at the fold of the elbow ready for the insertion of the cannula.

Continuous Intravenous Infusion (Venoclysis)

Useful as is the massive dose of intravenous saline the indications for its use are limited. It must be borne in mind that unless there has been a corresponding loss it is manifestly unphysiological to put into the circulation a pint of fluid more or less suddenly. In shock, dehydration from vomiting, oliguria, and many forms of toxæmia, a slow continuous flow of saline intravenously approaches the ideal, for we know exactly how much fluid the patient is receiving. The fluid can be given over a period of

days, and the rate of flow and the amount of fluid can be regulated with mathematical precision.

Continuous intravenous saline is valuable in the treatment of shock. In these cases an ampoule of coramine may be added to each pint of the saline solution with advantage. French observers have reported favourably on the results of adding adrenaline in doses of 5 minims of 1 in 1,000 solution to each pint.

Preparation of the Solution.—Obviously a solution which is introduced directly into the circulation must be absolutely sterile. But this is not enough: it must also be free from dead bacteria and other extraneous matter, such as fur from the sterilizer. Boiled tap-water does not fulfil these requirements, and reactions are bound to occur if it is used. Triply distilled water not more than a week old must be employed in all cases. It is, of course, equally important to have the sodium chloride sterile and pure. Tablets sold in tubes for the preparation of normal saline are not manufactured with a view to intravenous therapy. Sterile ampoules for making the solution are obtainable.* Leading manufacturing chemists now put up sterile normal saline in sealed litre bottles. When there is difficulty in obtaining fresh distilled water, and the facilities for sterilizing the somewhat bulky apparatus are not perfect (as in a private house), saline in this form, though comparatively expensive, has obvious advantages.

Saline or Saline and Glucose?—Normal saline solution alone meets most requirements. When glucose is employed we are introducing a substance into the circulation which requires katabolism, and if glucose is to be used there should be adequate reasons for its introduction: the patient must be in need of glucose, as one who has been starved, and only enough glucose for his immediate requirements should be introduced by the intravenous route. As regards insulin, if there is no reason to think that there is a deficiency of this hormone there is no need to give more.

Apparatus.—Special needles and cannulae for intravenous infusion are available. The ones shown in Fig. 5

FIG. 5.—Author's needle and cannulae. A, Needle for insertion into a vein by puncture; B, Cannula; C, Cannula, child's size. All the above are gold-plated to prevent corrosion. D, An interceptor for continuous intravenous saline.

will be found to be satisfactory. Every portion of the apparatus (see Fig. 7) must be freshly boiled and washed through with sterile water or saline before the reservoir is filled. New rubber tubing should be boiled, stretched, and washed through to remove chemicals, and boiled again before the apparatus is assembled. An interceptor—Fig. 5 (D)—is an integral part of the armamentarium: it should be freed of contained water from the sterilizer before the reservoir is filled. The whole apparatus must

be seen to be in working order and the filled reservoir suspended suitably before any attempt is made to prepare the patient for the reception of the saline.

TECHNIQUE

Choice of the Vein.—In general it is best not to use a large vein; one just a little larger than the cannula or needle is most suitable. A vein of the forearm is usually chosen. If no veins can be seen an incision should be made over the beginning of the internal saphenous vein; even in newborn infants one never fails to find this vessel just anterior to the internal malleolus. In patients who are restless, or may become so, the leg as a site for the infusion is preferable, for the lower limb can be splinted securely.

Inserting a Cannula.—In many emergency conditions the veins are collapsed; consequently it is necessary to expose the vessel. This is done through a small transverse incision, as already described. Full aseptic ritual must be observed, in the preparation both of the patient's skin and of the operator's hands; it cannot be stressed too often how vital it is for everything to be aseptic in this procedure. For subsequent smooth running it is recommended to flood the wound and moisten the cannula with citrate solution immediately before inserting the cannula into the vein. Once the cannula is satisfactorily in position the wound is closed about it. The cannula is now fixed to the skin by means of fine stitches passed through the slots near its base (Fig. 6).

Inserting a Needle.—If a needle, as opposed to a cannula, is chosen, it is a mistake to take the most prominent vein. One that is easily palpable but well obscured and supported by subcutaneous fat will be found to be less mobile and thus more readily entered. The large prominent veins of the aged are notoriously difficult to enter, and in these cases it is as well to transfix the vein transversely with a fine hypodermic needle before carrying out the puncture. The special needle is unfastened, the base being left attached to the tubing of the apparatus (Fig. 7). The needle is then placed on a Record syringe and a small amount of citrate solution is drawn up through the needle into the barrel. After a tiny nick has been made in the anaesthetized skin with a scalpel puncture of a vein is carried out, and this will be found easier with the syringe attached to the needle. In order to be certain that the vein has been entered blood is drawn up into the syringe, and a little citrate solution is then injected into the vein. The syringe is removed and the base of the needle connected to the adaptor at the end of the tubing. The needle is kept in position by suitable strips of adhesive plaster passed over the wings of the needle.

FIG. 6.

Keeping the Limb at Rest.—For the arm a posterior plaster strip well padded with Gamgee tissue with a turn around the wrist forms an ideal splint readily adapted to each individual patient. For the leg a posterior splint with a footpiece is very serviceable (Fig. 8). Alternatively, a Thomas's knee-splint can be used; this has the advantage of ensuring rigidity of the limb if the patient is inclined to be restless.

The Temperature of the Fluid.—In spite of the many ingenious devices that have been put forward for keeping the fluid warm the simplest appears to be the best—namely, the patient's leg or arm into which the saline solution is flowing is kept warm with a hot-water bottle

FIG. 7.

or an electric heating pad. In addition to simplicity this leaves the reservoir and the delivery tube in full view.

Rate of Flow.—The average rate of flow for an adult in need of fluid should be fifty drops per minute—that is, a quarter of a pint per hour, or six pints in the twenty-four hours. In urgent cases, for the first hour the rate of flow is often accelerated to 100 drops per minute to see how the patient responds. If the blood pressure is increased satisfactorily we are encouraged to proceed with the measure. When in doubt as to how much fluid the patient should receive the flow should be cut down to thirty drops a minute—that is, approximately three and three-quarter pints in the twenty-four hours—a dose which, at all events, is unlikely to harm him.

The Administration.—The actual administration is largely in the hands of the nursing staff. It is of paramount importance to be sure that the nurse appreciates the simple yet vital responsibilities connected with the care of the apparatus and the maintenance of strict asepsis. The nursing instructions are simple, and can be carried out by any conscientious State-registered nurse providing that she receives special instructions if she has not been trained in the method.

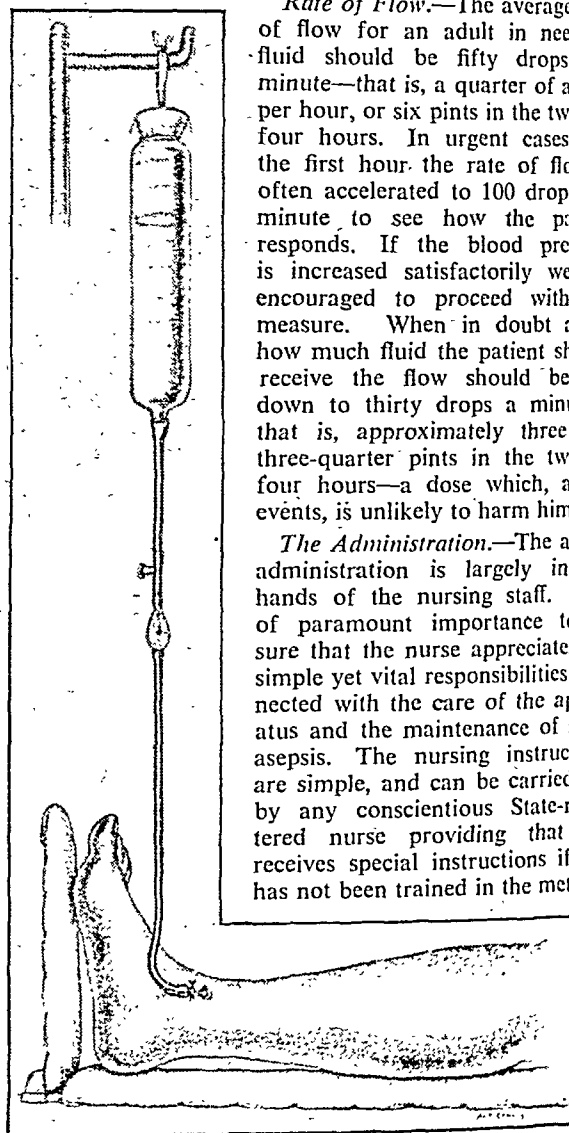

FIG. 8.—The apparatus in use. In very ill patients who are restless or may become so the limb can with advantage be placed in a Thomas's splint. (This apparatus is made by the Genito-Urinary Manufacturing Co. Ltd.)

NURSING INSTRUCTIONS

1. Every utensil used in the transfer of the saline to the reservoir must be absolutely sterile.
2. To prevent the entry of bacteria from the air the top of the reservoir must be covered with sterile gauze.
3. The reservoir must always be kept more than half full of saline.

followed the operative procedure in all but six: thirty-one patients in whom the condition was moderate had all improved, and in the twenty-nine extremities in which the condition was advanced there was subjective improvement in about 50 per cent. In none of these cases had there been any complications.

Dr. White touched briefly on two other conditions—auricular paroxysmal tachycardia and auricular fibrillation. He related the case of a child of 4 whose paroxysmal tachycardia developed at the age of 2. Novocain injection of the left stellate ganglion was carried out, and normal rhythm was restored. In another case, a woman of 70 who had had paroxysmal fibrillation for four years, bilateral injection of the stellate ganglia with alcohol and novocain gave a year's freedom from the attacks. He also related the case of a man in whom pressure on the right side of the neck produced syncope. The condition cleared up after infiltration of novocain along the bifurcation of the carotid.

Sympathetic Ganglionectomy in Raynaud's Disease

Sir THOMAS LEWIS took up first the question of sweating in Raynaud's disease. It was not his experience that patients with this condition sweated freely on their hands: many of them had hands of normal dryness. On the more general question, those who held that the vasomotor system was at fault believed that sympathectomy removed an abnormal vasomotor tone. While he agreed that sympathectomy was quite the correct treatment for many of these patients, he believed that it had its effect by removing not abnormal vasomotor tone but the normal vasomotor tone which almost everyone possessed, and it must have this tendency in cases of Raynaud's disease. Time had still to show whether sympathetic ganglionectomy, while it relieved these patients, could cure them. The rejoinder was made that when the ganglia were taken out a condition of hypersusceptibility to circulatory hormones was produced in the small vessels, and that if the operation failed it failed for that reason. When the argument was put in that way it must be disallowed. If it were true that the occurrence of the attacks in these patients was the result of increased susceptibility of the vessels to circulating hormones, then it would surely be true that all cases of sympathectomy, whether Raynaud's disease was originally present or not, would show Raynaud's phenomena subsequent to the operative procedure.

The fact of increased susceptibility of the vessels following ganglionectomy, to which he had drawn attention eight years ago, had been worked at considerably since then, particularly by Dr. White and his collaborators, and its results had been made the basis of Dr. White's later operative procedures. While he accepted the fact that the preganglionic operation was more beneficial to these patients, he did not believe that it was a better operation or gave greater relief than ganglionectomy. It did not touch the essential point that Raynaud's phenomenon was essentially local, due to a local cause. Some years ago he had stated that he did not think that, however extensive the operation of ganglionectomy was made, all cases would respond to it: there would be many left in which improvement might be achieved, but not cure. He made the same prediction now with regard to the operation of preganglionectomy. He had examined four cases in which the preganglionic operation for Raynaud's disease had been done. In all these cases, shortly after the operation, he had been able to induce attacks in the hand; he could not induce those attacks so readily as before operation, but he had not yet failed to produce a highly abnormal condition of the fingers. At the same time he had nothing but admiration for the enterprise which had led to these surgical operations, but on the question of the value of these operative procedures on the mechanism of the disease his original position was unaltered.

Surgical Intervention in Erythromelalgia and Other Conditions

Professor E. D. TELFORD spoke in particular of erythromelalgia, on which some work had been done in Manchester during the last few years. In 1878 Weir Mitchell published a paper on what he called a rare vasomotor neurosis of the extremities, and described a condition of hot burning feet, with pulsating arteries, dilated veins, intense pain on walking and standing, and intense hyperaesthesia. Twenty years afterwards James Collier followed with an account of ten cases of a similar type, but no real light on the subject was available until Lewis in 1933 published a long and careful observation and came to the conclusion that this was no disease but simply a susceptible state, that there were certain persons who had a threshold for warmth or heat which was much below the normal. Erythromelalgia was not a common condition.

A woman aged 22 was admitted to his ward with the story that since childhood she had been troubled with burning feet every summer, but in 1934 the condition persisted during the winter, and became so intolerable that she could not bear the bedclothes over the feet. The feet had the appearance of having just been removed from a hot bath. Various physiotherapeutic treatments were tried without effect: the patient was discharged but returned in 1936, begging that something might be done to relieve her condition. It seemed unreasonable to do an ordinary sympathectomy, but when it was considered that the condition might indicate some lesion of the vasoconstrictor mechanism it seemed worth while to make a trial of the procedure. Accordingly a one-sided sympathectomy was done in July, 1936, and the attacks on the operated side ceased. He waited for twelve months before carrying out the operation on the other side: this was duly carried out in July, 1937, and since then both feet had remained perfectly well.

The case suggested that sympathectomy was certainly worthy of trial in these rare but distressing instances. The speaker also touched on conditions of excessive sweating, and mentioned some remarkable cases of profuse but strictly localized sweating. One of these was a meter inspector who had to walk twelve miles a day and who had sweating of the feet to such an extent that he had frequently to take off his boots and wring out his socks. A lumbar ganglionectomy resulted in an immediate cure, and six years after operation he was perfectly well. Sympathectomy was an ideal treatment for these rare and very troublesome cases of excessive sweating. It was true there was an alternative in x-ray treatment, but he considered that to be a little too risky and liable to result in fibrosis or even in malignant change.

Professor J. R. LEARMONTH dealt with the subject of sympathectomy as applied to the alimentary and urinary tracts. The clinical problem was to convert disordered transmission into ordered transmission, and incomplete evacuation into complete. He described the procedures which had been applied: for the urinary tract renal sympathectomy, division of the presacral nerves; and for the colon, resection of the lumbar trunks, resection of the presacral nerve and inferior mesenteric nerves, or resection of the mesial branches of the lumbar trunks, this last the most selective and the least destructive. A proportion of good results had followed all the various types of operation he mentioned, and he advanced the view that at least in cases of achalasia there was room for the operation of sympathectomy as a part of treatment.

Discussion

Professor PATERSON ROSS said that they must all agree not only from the experimental point of view but from practical experience that preganglionic section was an ideal operation, but when it came to the treatment of Raynaud's disease—a special case—he agreed with Sir Thomas Lewis that there were disappointments in store for those who expected a cure. In his own experience, while many of the results were gratifying, others, for no

female patients suffering from various psychoses by the intravenous injection of typhoid-paratyphoid A and B vaccine. The conclusions reached are that T.A.B. vaccine is useless in schizophrenic and manic-depressive psychoses; that toxæmia as evidenced by confusion, occurring in association with any psychosis, may improve, but such improvement is uncertain; that pure toxic psychoses where bacterial infection is suspected as a primary cause do best, but treatment with this vaccine is only part of a general scheme, and that occasionally toxic-exhaustive patients who are severely ill derive tonic benefit from small doses.

Biochemical and Physiological Research

Looking at the communications as a whole, the main effort in research seems at present to be directed to chemical, biochemical, and physiological investigations. At Cardiff City mental hospital much work of this kind of high importance continues in progress. It includes work on narcotics and tissue oxidations, also on choline metabolism in the brain, with some interesting physiological findings. At St. Andrew's, Northampton, an investigation has been started on tissue culture of the nervous system in order to ascertain whether the method offers any promising lines of research into the functions of that system. The technical requirements are said to be difficult, but not insuperable. Numerous researches are being carried out at the Central Pathological Laboratory of the London County mental hospitals. One of them is on the selective vulnerability of the nervous system to various poisons and anaesthetics, a work of great importance which may extend over several years. Another is an investigation into the carbohydrate metabolism of various portions of the nervous system. One piece of work at this centre which has so far yielded only a negative result is an investigation into the possibility of the protection of mental hospital populations by administration of oral vaccines. So far the results do not give any reason for hoping for ultimate success in immunization by this method. One expensive and important research, assisted by a grant from the Rockefeller Foundation, consists in the production (in the course of treatment of general paralysis at Horton and Maudsley Hospitals) of therapeutic spirochaetocidal substances. The results are stated to be in process of publication.

Therapeutics

Some sixty or more items in various communications bear directly on treatment, and a dozen of these are concerned with the malarial treatment of general paralysis. At the Lancashire county mental hospital, Winwick, there has been a follow-up of old neurosyphilitics, only those cases which were admitted to hospital from ten to fourteen years ago, when the treatment consisted of malaria only, being included. The conclusions suggest that malarial therapy results in about one-third of the cases being discharged, and that whereas some 90 per cent. of non-treated cases die during the first two years after admission, half the treated cases live at least five years, and nearly a third a full ten years.

Prolonged narcosis as a line of treatment continues to receive much attention, and there are many references to somnifaine and other drugs. At Dorset county mental hospital a painstaking investigation into therapeutic narcosis with soneryl has been carried out, and a favourable report is given. The relative efficiency of luminal and prominal has been investigated at Warwickshire and Coventry mental hospital; the results of substituting prominal for luminal have been on the whole disappointing. From Newport, Mon., come observations upon the use of anti-rabies vaccine in epilepsy: two out of three cases showed some improvement mentally and a slight decrease in the number of fits.

Comparatively few psychological observations are recorded, though these include some very special ones from the psychological department at Bethlem. At Stoke

Park Colony, Bristol, under the Burden Research Trust, some 3,500 normal school children have been examined and group-tested, and nearly half of them further submitted to the Binet mental tests. An investigation on intelligence in relation to family size has been completed. From the Royal Eastern Counties Institution comes a study of mental ability in a rural community, with a view to investigating the effect of paternal occupation, illegitimacy, and parental consanguinity. This was an area in which two-thirds of the children belonged to a group interrelated by marriage, but this did not appear to affect intelligence as compared with unrelated children. No detail in mental medicine is frivolous, and therefore a note from Wonford House Hospital, Exeter, on the therapeutic value for women patients of a hairdressing room, where a permanent wave made melancholic and confused patients think they must be getting better, is worthy of inclusion among more highly scientific communications.

RESEARCH IN BLOOD DISEASES

Grants and Scholarships

The trustees of the Lady Tata Memorial Fund invite applications for grants and scholarships for research in diseases of the blood, with special reference to leukaemia, in the academic year beginning on October 1, 1938. Grants of variable amount are made for research expenses or to provide scientific assistants to senior workers. Scholarships are awarded as personal remuneration; their value will not ordinarily exceed £400 per annum for whole-time research, with proportionate adjustment for work on a part-time basis where this is approved. The grants and scholarships are open to workers of any nationality.

Applications must be submitted before March 31, 1938, and the awards will be made by the trustees in June. Further particulars and forms of application may be obtained from the secretary of the Scientific Advisory Committee, 138, Bedford Court Mansions, London, W.C.1.

Reports of Societies

SURGERY OF SYMPATHETIC NERVOUS SYSTEM

At a meeting of the Medical Society of London on January 24, with Mr. J. E. H. ROBERTS in the chair, the subject of discussion was recent advances in surgery of the sympathetic nervous system.

Dr. J. C. WHITE (Boston, Mass.) confined his contribution for the most part to a consideration of Raynaud's disease. He showed a series of photographs of successive phases of this condition—symmetrical colour changes, cyanosis, and excessive sweating. A large number of young people suffered from cold, clammy hands and feet—Uriah Heep was such a person: "His damp, cold hand felt like a frog in mine." In many the condition disappeared as they grew older, but in some it advanced into typical Raynaud's disease. It was important to note that many of these people showed excessive sweating, not of the whole body but of the hands and feet. Dr. White proceeded to give his results with lumbar ganglionectomy for Raynaud's disease in the lower extremities. The total number of cases operated on was eighteen, and the results, up to six years, were excellent in seventeen. One case gave a fair result: there was fibrosis from scleroderma. In a case which had been followed for six years the pre-operative temperature of the toes was 71.5° F.; the post-operative temperature was 93.2° F., and six years later it was 93° F. In preganglionic sympathectomy for Raynaud's disease of the hands the results in sixty-four patients, involving 106 extremities, were on the whole satisfactory. In forty-six of the extremities in which the disease was only in a mild form excellent results

total of seventy-five a family history of rheumatism was given in fifty-four. It was probable that the benign character of the psoriasis had diverted attention from its relationship to rheumatic affection. Psoriatic patients did not appear to develop mitral stenosis. For years she had been on the watch for a psoriasis case developing a rheumatic heart, but had failed so far in her search. The lesion in psoriasis and the rheumatic nodule evolved in a similar manner; the ultimate difference between them was attributable to differences in the types of cells concerned. Both lesions might persist to abscess formation, which in the case of the experimental rheumatic nodule had been shown to occur in a sensitive animal, proving that allergy played some part. In relation to rheumatic infections three features of the clinical manifestation of psoriasis were of special interest: (1) a latent period of some weeks between the time of the initial infection and the onset of the eruption; (2) the initial distinctive type of the eruption; and (3) the immunity in after-life from such internal complications as valvular heart disease, pointing to some special relationship between psoriasis and the rheumatic infection—a conclusion not invalidated by the fact that psoriasis could and did occur from other causes.

Treatment at Spas

Dr. WILLIAM YEOMAN confined his remarks to the treatment of cases at spas. Since the advent of light and x-ray treatment there had been a notable diminution of skin cases coming to spas. Shortly after the war and during the depression gout became a rare disease, and for some time hardly a case was seen at Harrogate Royal Baths Hospital. The beneficial effect of the waters of Harrogate was first produced by stimulating the action of the liver, and secondly by immersion in the waters. With acute gouty eczema it was impossible at first to give sulphur baths, but after a week or so a cautious start might be made. The association of rheumatism and psoriasis might be a coincidence, but when the two conditions did occur in the same subject there must be a common factor in causation. One frequently saw the rheumatism improving and the psoriasis getting worse, or vice versa, and it was usually the infective rather than the degenerative type of arthritis in these cases. Owing to the tendency of psoriasis to wax and wane it was difficult to assess the value of any treatment, but he felt that this condition was very suitable for treatment at a spa. He stressed the view that spa treatment acted by altering the metabolism of the patient, and was therefore more suitable for skin lesions associated with a disturbance of metabolism.

In the course of some general discussion Dr. N. BURGESS referred to the almost invariable affection of the nails in arthritic patients. In the treatment of psoriasis in acute cases with spreading lesions the appearance of new lesions was a contraindication to ultra-violet light; if new lesions were not appearing this form of therapy was exceedingly useful. Dr. AGNES SAVILL referred to a case in which there had been a steady improvement in the psoriatic condition with ionization. Dr. G. D. KERSLEY was surprised to hear Dr. Hunt's high percentage of family histories. He wondered what was taken as constituting a family history. It was a very common thing for people to reply in the affirmative when asked if they had a relative who had rheumatism. Dr. L. C. HILL said that, to illustrate the inadequacy of statistics, he had lately examined at his own hospital the statistics for gout over the last fifty years. The incidence varied enormously. For ten years it would remain at about 2 per cent., and then go up during the following ten years to 12 per cent. He discovered that the alterations in the percentages coincided with changes in the personnel of the staff. He had personally made a list of 140 cases of rheumatoid arthritis, and had found only two with psoriasis. Dr. HUNT described the care with which her assessment of family histories had been taken.

PRIMITIVE SIGHT AND HUMAN SQUINT

At a meeting of the Liverpool Medical Institution on January 20, with the president, Professor R. E. KELLY, in the chair, Mr. F. BERNARD CHAVASSE read a paper on primitive sight and human squint.

Mr. Chavasse brought forward evidence of the existence of binocular vision in all sighted vertebrates, and of its ultimate refinement, bifoveal vision, which was found not only in a small class of the mammalia but in some birds, reptiles, and even fishes. Overlapping was present in the binocular field of all vertebrates. No one had ever observed a purely monocular following movement in response to a purely monocular, visible, moving stimulus, even in the chameleon. It was safest to think of the "fusion" of the two unocular patterns as a physical affair—a fusion in the appropriate oculo-somatic motor response. Similarly, a psychological cause was not required to explain the physical facts of the comparative anatomy of the optic chiasma. It was a matter of effecting an economy in the neuron architecture required to produce the appropriate movement.

Evolution of Binocular Vision

The primitive vertebrate was as blind as a bat, which did not mean that it was unable to avoid obstacles, even in complete darkness, as a bat did. The barely defined visual fields of the two structures, which in a translucent body were as yet hardly eyes, had, if anything, a vague total overlap. By the time the fields became defined, with a maximum overlap where the prey was, the eyes had become well endowed with muscles. These muscles were developed to keep the eyes fixed relative to the panorama, in spite of movements of the head, so that from the first the two eyes were held in conjugate immobility under the influence of the compensatory (labyrinthine and "neck") reflexes. On the conjugated bi-retina fell various light stimuli, which came to be signals for the enhanced performance of reactions previously effected by non-retinal stimuli alone. He held that by applying three principles of Pavlov in the sphere of comparative physiology an orderly emergence of the various ocular reflexes could be traced; examples were given.

If binocular vision, so far from being the perquisite of man and the great apes, was so primitive as to be universal in the vertebrates, it followed that the developmental tendency towards it, manifest in the individual infant, should be very powerful. Its full development was ordinarily complete at the age of 3, and at the age of 6 or 8 years had acquired a certain unconditional fixity. If the eyes of an infant were forced into a position of squint they became confirmed in their faulty position by one or other variety of perverted binocularity. In the positive aspect of this (as distinct from the negative, amblyopic aspect) there developed, for instance, a perverted correspondence between the fovea of one eye and some eccentric spot with poor visual acuity in the other eye. The perverted reflexes were often perfected during the first three years of life and became hopelessly fixed at an early age. The eyes could be straightened for cosmetic or psychological reasons after this early age had passed, but the squinting eye was generally amblyopic. The ingrained perverted reflexes fought against the surgeon, tempting him into measures risking immediate or secondary divergence; there was as a rule no memory of normal correspondence to effect a physiological bond between the artificially straightened eyes, and it was much too late for such a bond to develop *de novo*.

Time of Operation

It was therefore often necessary, in cases not immediately relieved by occlusive and refractive methods, as well as in the great mass of unrecovered paralytic cases, to operate in very early childhood or in infancy, in order to give the ocular reflexes the chance of developing on

clear reason, were unsatisfactory. He had been much disappointed in one early uncomplicated case in which he was quite satisfied that he had performed the operation he intended to perform, but the woman still had to wear gloves while doing her housework. Mr. H. T. SIMMONS said that a series of patients had been tested for adrenaline sensitization before and after operation, and it was found that the sensitization decreased with time. In cases of Raynaud's disease clinical relapse began to appear six or nine months after the sympathectomy.

Dr. H. LETHEBY TIDY, as a student of Dickens, joined issue with Dr. White in suggesting that Uriah Heep wrung his hands because they were sweating. The whole history suggested that Uriah Heep, a sexual depressive, was against the world, and the wringing of his hands was a psychological action. While he did not deny that sweating occurred in Raynaud's disease it did not always occur, and so far from the patients having a tendency to wring their hands they usually kept them quietly in a bent position.

Dr. WHITE, in reply, urged that sweating of the hands was a frequent symptom in Raynaud's disease, though he agreed that occasionally patients with entirely dry hands were found. Nine out of ten of the early uncomplicated cases, without sclerodermia and in young individuals, showed an extraordinary degree of sweating. As for Uriah Heep, Dr. Tidy had perhaps forgotten another significant reference: "His lank forefinger followed up every line as he read, and made clammy tracks along the page (or so I fully believed) like a snail"!

which possessed certain distinctive features. The arthritis resembled clinically and radiologically atrophic arthritis, and the deformities might be very severe. One peculiar feature was the tendency to involvement of the terminal interphalangeal joints of the fingers and toes, which was rare except in severe and late cases of non-psoriatic arthritis, and the marked psoriatic changes in the nails adjacent to the affected joints. Moreover, intermittent hydrarthrosis of the larger joints was commoner than in non-psoriatic arthritis. In some cases focal streptococcal infection appeared to be the chief aetiological factor, as in one case observed in which infection from numerous dead teeth was unquestionably responsible for both the psoriasis and the arthritis, but in other cases this was not apparent.

In conclusion Dr. Barber touched upon other eruptions in association with gout, particularly a condition of the palms and soles which appeared to be a genuine gouty manifestation. It was characterized by an erythema of the palmar and plantar surfaces, extending on to the lateral surfaces of the hands and feet; by hyperkeratosis, occurring chiefly at sites of pressure; and by subjective symptoms of itching and burning. Although commonest in middle or late middle life, it might be met with in young adults and the aged.

Pigmentary Disturbances of the Skin

Dr. KERR PRINGLE, dealing with pigmentary disturbances of the skin, said that the frequency of concentrated patches of pigment occurring in cases of rheumatoid arthritis had often been pointed out. The dominant tints of the face were orange and citron, and a bronze shadow might be detected on the back of the hand. The unexposed parts of the body might be darkened in patches. Patients would say that the spots appeared at the same time as the rheumatoid symptoms. He had been on the look-out for many years for cases of rheumatoid arthritis presenting pigmented appearances, and he did not think these were as common as was supposed. He also mentioned Heberden's nodes, which were considered to be osteo-arthritis in nature. The initial symptom consisted of redness on the lateral aspect of the terminal joints of one or more digits. Occasionally rounded cyst-like bodies were seen, having the appearance of sago grains, on the knuckles of rheumatoid arthritis. These contained clear fluid, were not painful, and appeared gradually to become absorbed. He had no explanation to offer as to their nature. Patients with rheumatic disorder often stated that their chiropodist had told them that their corns and callosities or deformities of their nails were due to rheumatism. Was there any truth in that? He had always believed that corns and callosities were produced by friction or pressure, the most probable cause being badly fitting shoes or flat-foot. Nor could he believe that rheumatism *per se* had any effect on the nutrition of the nails. He made the further observation that many gouty patients stated that they were much better in general health when the skin condition was active. Treatment should be applied to the general condition—that is, the gout—rather than to the associated skin condition.

Relation of Psoriasis to Rheumatic Infection

Dr. ELIZABETH HUNT confined her remarks to some aspects of psoriasis and its relation to rheumatic infection. It had long been recognized that psoriasis was often associated with rheumatism of various forms occurring in the same individual or a near relative, but not many published records had been available. In 1933 she had detailed a series of fifty-three cases of psoriasis in which the family and personal history in regard to rheumatic manifestations was set out, and a family history of rheumatism, using the word in its broadest application, was obtained in a large proportion. This had been confirmed in a further twenty-two cases since that date. Out of the

SKIN MANIFESTATIONS IN RHEUMATISM

At the Royal Society of Medicine on January 21 the Sections of Physical Medicine and Dermatology combined for a special discussion on the skin manifestations in rheumatism.

Dr. H. W. BARBER, after a brief survey of the subject, considered in detail the question of psoriasis in direct association with rheumatoid arthritis. Apart from the syndrome arthropathic psoriasis, rheumatic symptoms were common in psoriatics. As with rheumatism, the provoking factors in the skin condition clearly varied in different cases, and from the therapeutic standpoint there was as yet no specific treatment. For the present psoriasis might be regarded as a non-specific cutaneous reaction, the tendency to which was hereditary and familial in about 30 per cent. of cases. The eruption might coincide or alternate with various types of rheumatism—fibromyositis, rheumatoid arthritis, osteo-arthritis, and gout. Provoking factors apart from heredity might include environment, diet and errors of metabolism, and acute and chronic infections. A comparison might be made between the influence of a streptococcal infection upon psoriasis and its role in rheumatism. In rheumatic fever and in the psoriasis of childhood, streptococcal infection of the throat played a very important part. The two diseases might develop after a "silent" period of about one to three weeks following either tonsillitis or scarlet fever, and in both subsequent attacks of tonsillitis were followed by recrudescences even in adults. In rheumatoid arthritis and in psoriasis beginning in adult life, focal infection in the teeth, nasal sinuses, or elsewhere might be the chief provoking factor. On the other hand, in many adult cases of psoriasis there was no evidence that streptococcal infection played any part whatever, and the same was true of some cases of rheumatoid arthritis.

Psoriasis Arthropathica

Dr. Barber went on to say that apart from the association of psoriasis with various forms of rheumatic disease and gout, there was a syndrome—arthropathic psoriasis—

sputum. It has latterly been recognized that the pneumococcus can produce a haemolysin which is as active as that of the streptococcus, and work on the differentiation of these two haemolysins is proceeding, one possible practical outcome being the production of a more effective streptococcal antitoxin than has yet been available. From the department of experimental pathology and cancer research Professor R. D. Passy reports that it has so far proved impossible to reproduce Fibiger's work on the association of cancer with the parasitic worm. Further support has been obtained for the hypothesis that cancer tends to start in areas in which defective blood circulation has been induced. At least one, and possibly two, hitherto unknown enzymes have been shown to be concerned in glycolysis in muscle extracts. No success was obtained from using colchicine in the treatment of naturally occurring tumours, and no evidence was obtained that the injection of prolactin or progesterin could augment the effect of oestrone in the development of breast tumours in mice.

The New Westminster Hospital Medical School

The fine new quarters for the Westminster Hospital Medical School are now nearing completion. With the new nurses' home they form one large block on the west side of the open space known as St. John's Public Gardens, Horseferry Road, Westminster. The main hospital building is in course of erection on the east side of the large site that has been cleared. The medical school, with its nine stories, provides everything for study and indoor recreation that modern ideas demand. The basement contains a large lecture theatre to seat 250, gymnasium, billiard-room, squash racket courts, shower baths, changing and drying rooms, and a radon room. On the ground floor are the main students' common room, smoking room, and refectory. The library and museum and adjoining demonstration room are on the first floor, with galleries on a mezzanine. On the second floor are the main classroom, small lecture theatre, and administrative offices. The histological laboratories, workshops, etc., are on the third floor; the general pathological laboratory and directors' rooms on the fourth floor; the biochemistry department and post-mortem room on the fifth floor; the physics department and research room and the operative surgery room on the sixth floor; research laboratories, photographic rooms, animal rooms, and roof garden on the seventh floor. On the fifth and sixth floors there are also bedrooms for thirteen resident medical officers, with gas-fires and a constant hot-water supply to the washbasins in each, and two bathrooms. All money used for the furnishing and equipment of the students' rooms in the medical school has been specially subscribed for the purpose and has entailed no charge on the hospital's funds. The new nurses' home, admirably laid out and decorated, will be opened by Queen Mary on March 1, and the new medical school by the Earl of Athlone in April.

Fees for Anaesthetists at L.C.C. Mental Hospitals

The Mental Hospitals Committee of the London County Council, in submitting certain proposals relating to the medical staff at Maudsley Hospital, states that one of these proposals—regarding fees for anaesthetists—has a wider bearing on the mental services as a whole. It is proposed that the fee of one guinea a session hitherto paid to anaesthetists in connexion with minor operations at Maudsley shall be increased to accord with the fees payable in the hospitals service—namely, two guineas for visits of less than three hours' duration, three guineas for visits of three hours or more but less than four hours, and four guineas for visits of four hours or more. It is also proposed that this scale shall be applied generally in the mental hospital services with effect from January 1. Other proposals relating to Maudsley only are that the part-time medical officers for out-patient diagnostic work

shall be employed for three sessions a week and paid at the sessional rate as fixed for part-time consultants in the general hospital service—namely, £275 a year. Two part-time medical officers are to be employed for the treatment of in-patients by psychotherapy, each for five sessions a week at a salary of £300 a year. A further proposal relates to members of the Maudsley Hospital staff who are granted leave to go abroad to study special problems of psychiatric treatment with the aid of grants from the Rockefeller Foundation or some similar source. On their return they are to be relieved of part of the routine clinical duty which ordinarily would absorb the whole of their time at Maudsley, in order that, in the mental hospital service generally, with its great wealth of clinical material, they may be enabled to follow up special lines of research and inaugurate methods of treatment based on their studies.

Central Midwives Board

At the January meeting of the Central Midwives Board for England and Wales approval as lecturers was granted to A. L. Gunn, M.D., F.R.C.S., Albert Davies, M.D., F.R.C.S., and Thomas Emmett Lennon, M.D. Approval for the purpose of providing instruction in the essentials of obstetric analgesia and in the use of a recognized apparatus was granted to the Leeds Maternity Hospital and the Leicester and Leicestershire Maternity Hospital. To a letter from the supervisor of midwives of a local authority, asking for a ruling on points submitted, the Board replied:

- (1) That if a midwife having booked a case calls in medical aid on account of an abnormality during pregnancy and the doctor decides that it is advisable that he should attend at the confinement, it is in order for the doctor, with the consent of the midwife, to take over the case forthwith and for the midwife to act thenceforth in the case as a maternity nurse.
- (2) That a midwife is not entitled under any conditions to issue a medical aid form in a case in which a doctor has already been summoned by the patient or her relatives or her friends.

In response to an inquiry from a local supervising authority the Board decided to inform the authority:

- (1) That the Board has always held that a midwife, as in the case of a doctor, has the right to refuse to book a case which, on any grounds reasonable or unreasonable, she does not desire to attend; but that this view does not extend to patients on whom attendance may be demanded on humanitarian grounds or a case in respect of which the midwife, as regards attendance, owes a duty to some other body, person, or authority responsible for the provision of an adequate midwifery service.

- (2) That the rules of the Board provide that if a midwife is summoned to a case of miscarriage she should not deal with such a case otherwise than as the assistant of a medical practitioner, except in an emergency when a doctor cannot attend.

Birth Control Report

The seventh annual report for 1937 of the National Birth Control Association (president, Lord Horder), with which is incorporated the Birth Control Investigation Committee (chairman, Sir Humphry Rolleston), records the visit of a joint deputation on February 2 to the Minister of Health asking him to use his powers and influence towards the establishment by local health authorities of gynaecological clinics to deal with the medical care of married women, at which advice on contraception would be available to those women to whom further pregnancy would be detrimental to health. In May the Minister issued to maternity and child welfare authorities a circular (No. 1622) on maternal mortality. In this he stressed the importance of post-natal services, stated that post-natal sessions should be held at every ante-natal clinic, and mentioned the possibility of giving contraceptive advice at post-natal and gynaecological clinics. Following the issue of Circular 1622 a letter was sent by the National Birth Control Association to all maternity

normal lines before their place had been usurped by ineradicable perversions. Photographs were shown of one of several operations which had emerged from these considerations, each designed to produce a particular effect and all specially evolved for treatment in earliest childhood and infancy. Mr. Chavasse said that he did not presume to ask for the acceptance at its first presentation of a novel view of development of the ocular reflexes, let alone for the universal adoption of particular operations by already experienced surgeons. But he did ask for the application by the general practitioner of a principle on which all ophthalmic surgeons were in solid agreement—namely, the immediate investigation of any case in which even the suspicion of an occasional squint had been aroused. Infants might squint from wind as adults did from anger, but as a rule the occasional glide meant that the ancient edifice of binocular vision was already rocking at its foundations.

In the discussion which followed, Dr. C. ALSTON HUGHES contrasted the demands of the new with those of the old methods of operating, and drew attention to the possibility of unpleasant subjective symptoms which might arise from hyperphoria following the more complicated methods, even when the cosmetic result was quite satisfactory. At the same meeting Dr. DONALD OWEN read a short paper on a case of hyperostosis frontalis interna.

Local News

SCOTLAND

Hospitals for Civilian Casualties in Air Raids

As announced in the *Journal* of January 22, (p. 182), the Government, with a view to making the fullest use in an emergency of existing hospital facilities and arranging for any necessary expansion, has decided that a comprehensive survey of the hospital accommodation of the country should be made. The Department of Health for Scotland, which is undertaking the survey in that country, has announced that Lieutenant-Colonel A. D. Stewart, superintendent of the Royal Infirmary, Edinburgh, and Dr. J. C. Knox, medical superintendent, Aberdeen Royal Infirmary, will assist the medical and other officers of the Department who have been detailed for the work. The survey will cover all hospitals and similar institutions, local authority or voluntary, and, so far as time permits, each institution will be surveyed by a medical officer and a lay officer in association. The country has been divided into Special Hospital Districts, and the officers responsible for each of these are: *Glasgow and the West*: Dr. T. Ferguson and Mr. J. Mason Allan; *Edinburgh and the South-East*: Lieutenant-Colonel A. D. Stewart and Mr. J. B. B. Brown; *Dundee and the East*: Dr. E. Watt and Mr. N. W. Graham; *Aberdeen and the North-East*: Dr. J. C. Knox and Mr. P. P. Kemp. *Highland Region*: Dr. Shearer and Mr. A. Smail. The General Board of Control for Scotland will be responsible for the survey of mental hospitals and mental deficiency institutions, and the inspecting officers will be the commissioners and deputy commissioners of the Board.

Canniesburn Hospital for Paying Patients

The auxiliary hospital and Merton convalescent home of the Glasgow Royal Infirmary, situated at Canniesburn on the outskirts of the city, was opened by Sir Iain Colquhoun on January 18. Sir James Macfarlane, who presided, said that in planning the section for paying patients they had borne in mind the possibility of extension, and the administrative block, kitchens, electric department, and heating installation had been devised on

a scale well beyond the present requirements. The accommodation for paying patients comprised forty-six single rooms, two rooms for two beds, and four for four beds. The hospital stands in grounds extending to fifty-five acres, which were purchased and presented by Sir James Macfarlane and his brother, Mr. George W. Macfarlane. The building consists at present of three blocks two stories in height linked by covered corridors. The part for paying patients contains sixty-six beds and the convalescent home has accommodation for eighty beds. The charges to cover both maintenance and nursing will be at the rate of three guineas per week for a bed in a four-bedded ward, four guineas in a two-bedded room, and five guineas for a single room.

Gifts to Scottish Universities

Edinburgh University Court, at a recent meeting, gratefully accepted the gift of Dr. J. Donald Pollock of the premises formerly used as Bristo Church in the neighbourhood of the New University Buildings, to be available for the secular purposes of the University with special regard to the requirements of the Students Representative Council and of students' associations and societies. The hall is to be known as the Pollock Memorial Hall, in memory of the donor's father and mother. Dr. Pollock also presented a number of steel-framed plate-glass cases for the exhibition of specimens in the forensic medicine department. The Court also accepted the bequest of the late Sir John Thomson-Walker of a collection of 2,500 engraved portraits of medical men and a collection of books dealing with the history of medicine, together with a sum of £500 to provide accommodation for the collection. Aberdeen University benefits to the extent of half of the residue of the estate of the late Sir Ashley W. Mackintosh, who was Emeritus Professor of Medicine at the University. He left £35,482, and his will, in addition to providing legacies for the Aberdeen Joint Hospitals Fund, Maternity Hospital, and Royal Hospital for Sick Children, directs that the legacy to the University should be used "for the purpose of continuing and furthering the study and teaching of clinical medicine along the old-fashioned lines of Bright, Sydenham, etc."

ENGLAND AND WALES

Pathological Research in Leeds University

In their annual report for 1936 on the work of the department of pathology in Leeds University, Professors Matthew J. Stewart and J. W. McLeod indicate the continuous rise in the number of students attending the various systematic courses. The research work in progress includes the accumulation of data relating to the various forms of silicosis and silicatosis, and the question of the relative incidence of bronchial carcinoma in these patients continues to be studied. Some success has been obtained in the use of artificial light for the photochemical production of gold sols. Some patients with renal calculi were shown to have an increase in the blood calcium figure, which has been attributed to hyperparathyroidism. On the other hand, an increase of parathyroid tissue in certain cases of renal disease without calculi has been reported, rendering it possible that the hyperparathyroidism accompanying the appearance of calculi may be secondary to renal disease. This investigation has therefore been extended to include a study of the blood calcium content in various types of renal disease. No evidence has been obtained that the epithelial metaplasia occurring in the cervix uteri in disease, though simulating early carcinoma, is malignant or even pre-cancerous. Gold treatment of chronic arthritis and its effect on capillary endothelium and the blood continued to be investigated. A useful modification of the Weigert-Sheridan method of staining elastic fibres has been devised, and has proved particularly useful for the detection of elastic tissue in the

Correspondence

Schick Relapse after Diphtheria

SIR.—The interesting observation made by Dr. F. Pygott in your issue of January 15 (p. 120) moved me to look up some similar results recorded in 1931 in serum-treated diphtheria patients. Of fifty-three patients tested simultaneously with two different toxins between the twenty-eighth and fifty-fifth days after antitoxin, three were Schick-positive, and in fifteen tested after the fifty-sixth day five were positive, so that in sixty-eight patients the Schick reaction was positive in 11.7 per cent. after a definite attack of diphtheria. Our experience with the earlier prophylactics showed that antitoxic immunity to diphtheria is slow in developing. It may be suggested, therefore, that the same is true after the natural disease, and that if Dr. Pygott's and my own patients had been Schick-tested at a much later date the proportion of negative reactors would have been higher. Against that, however, we can set the figures of Ker and McGarrity (1924), who found that in 157 individuals with a previous history of diphtheria 46.4 per cent. were Schick-positive, and also those of Benson (1924), who reported that of 245 children with a similar history 48 per cent. were positive. Doubtless if accurate records pertaining to these histories had been available it would have been found that in not all instances was the diagnosis of the notified disease confirmed; but even making allowance for these a goodly proportion of indisputable cases of diphtheria would have remained, and it is a curious reflection that a natural attack of the disease should give inferior results so far as immunization is concerned to an adequate course of the most recent antigens. The plain fact is that second attacks of diphtheria are not uncommon, and this is not so widely appreciated as it might be. Such results as Dr. Pygott and I have quoted indicate their possibility. The practical points which seem to emerge from them are, first, that an authentic history of previous attacks should not be regarded as a ground for regarding immunization as unnecessary, and such subjects should be at least Schick-tested; secondly, that a definite history of previous attacks should not be regarded as excluding the diagnosis of diphtheria. In several instances in my own experience the results of such an assumption have been serious.—I am, etc.,

City Hospital, Edinburgh, Jan. 24.

ALEX. JOE.

Early Diagnosis of Diphtheria

SIR,—The letter by Dr. H. J. Fardon in your issue of January 22 prompts a note on this problem so often discussed.

Some years ago an intensely interesting study of some thousands of cases of death from diphtheria was made in the U.S.A., the assumption being that if the diagnosis were made and a proper dose of serum given sufficiently early the mortality would be virtually nil. An attempt was made to find why the delays had occurred; naturally the largest percentage lay with the parents who failed to report "suspicious illnesses" sufficiently early. Dr. Fardon suggests that owing to our present medical arrangements delay may occur even after the doctor is called in. All the relevant arguments have appeared in your columns from time to time. If the doctor delays in giving serum he risks the life of his

patient, for we know from carefully controlled animal experiments that if a certainly lethal dose of toxin is given very few hours remain in which even a huge dose of antitoxin given intravenously can save the animal. If, on the other hand, the doctor gives serum to a patient whose sore throat is caused by streptococci or Vincent's organisms, and the patient later suffers from serum rash, the doctor faces an awkward dilemma.

The whole solution seems to lie in very early diagnosis. In an ideal community the diagnostic laboratory would be open day and night, and the pathologist could report immediately that the smear showed predominantly diplococci and streptococci or Vincent's organisms. By the use of the Folger-Solé swab he could detect the presence of diphtheria bacilli in some cases within four or five hours, and then aid the practitioner. The provision of such diagnostic facilities would be somewhat comparable with the arrangement made in America for the rapid typing of pneumococci in pneumonia. It is for our medical leaders to consider to what extent such a scheme is practicable, for it would be costly and troublesome.

As a compromise it might easily be possible to include on the notification form for diphtheria a few questions to be answered by the doctor. When was the first visit made? How long had the patient been ill previously? When was the first dose of serum given? How much serum was given? Was a swab sent for diagnosis before serum was given, and when was it sent? The study of the answers to these questions by each M.O.H. and a periodical confidential report on the analysis to the whole of the doctors in the area would probably serve a useful purpose.—I am, etc.,

Jan. 26.

BACTERIOLOGIST.

Silicosis Inquiry in South Wales: A Disclaimer

SIR,—During the past week several newspapers have published inaccurate accounts of the progress of the investigation into silicosis in the South Wales coalfield which is being promoted by the Medical Research Council with the assistance of their Industrial Pulmonary Disease Committee. These include a statement attributed to "a member of the Pulmonary Diseases Board" (apparently meaning one of the investigators working under the direction of the Committee) to the effect that the results of the inquiry will make possible an immediate reduction of over 80 per cent. in the incidence of silicosis in the anthracite coalfield. The facts are that the investigation is still in an early stage; that the results cannot yet be assessed; and that no such opinion as that purporting to be quoted has been formed. No interview has been given to the Press, and the alleged statement has not been made by the investigators.—I am, etc.,

E. MELLANBY,

London, February 1. Secretary, Medical Research Council.

Rehabilitation Centres for Injured Workmen

SIR,—This subject has been investigated by the Joint Committee of the British Medical Association and the Trades Union Congress, and the memorandum subsequently presented to the Government Interdepartmental Committee was very carefully prepared. The statistical estimates included in it are as exact as it is possible to make them, and the figures mean precisely what they say.

Rehabilitation Unnecessary.—A complete recovery and the return to original work is possible even without rehabilitation treatment, either because the injury is trivial or because the victim is not engaged in heavy industry, in 70 per cent. of cases.

and child welfare authorities which have not yet taken action under previous memoranda of the Ministry of Health. Out of 423 such authorities, ninety-five now have post-natal, gynaecological, or birth control clinics; eighty-six refer cases to voluntary clinics, private doctors, or hospitals; thirty-four give grants and/or lend premises to voluntary clinics; some do more than one of these things. In addition, forty-five stated that they give advice, but have no clinics or special arrangements; and 169 authorities do nothing. The report is issued from 26, Eccleston Street, London, S.W.1, and gives brief details of the year's activities and finance.

NEW ZEALAND

[FROM OUR CORRESPONDENT IN WELLINGTON]

Maoris and Tuberculosis

Tuberculosis in the Maori race presents a difficult problem. It is impossible to enforce the Health Act in small Maori settlements where housing and sanitation are primitive. Hutments now being supplied by the Government as an experiment represent a middle course between communal life, with its risks of infection by chance contact, and complete segregation of cases of active tuberculosis, which is objected to by the Maori people. The huts are not unlike those supplied to railway construction camps. Each has two windows and a fireplace. Except in the case of indigent natives the infected persons or their relatives are expected to provide suitable furnishing. The hutments will be under the control of the medical officers of health, and special nurses will make periodical visits to advise on any problems and watch the progress of the cases. Hitherto the tendency has been for patients who improve under hospital or sanatorium treatment to suffer a relapse on return to the native settlements. In spite of the tuberculosis menace the Maori population is increasing.

Medical Research

The Government has established a Medical Research Council under the provisions of the Health Act. A statutory function of the Health Department is to promote or carry out researches and investigations in matters concerning the public health and the prevention or treatment of disease. The members of the council are all medical except the Director-General of Scientific and Industrial Research. The council will act solely in an advisory capacity to the Minister of Health and will not control expenditure. *Ad hoc* committees will be appointed as part of the organization to supervise each investigation, and adequate funds will be provided by the Government. Preliminary work of investigation has already been done by way of research under the auspices of the Department of Health. Subjects for present and future investigation include nutrition, tuberculosis, goitre, dental caries, hydatid disease, cancer, and undulant fever. It is not intended by the council to provide funds for buildings, but, if approved, full costs of investigation will be allowed, including the salary of the research worker and the cost of equipment. From 1924 to the present time the Government provided only £13,239 for medical research in New Zealand, and the payments were intermittent. Now it is certain that medical research will be on a more definite and liberal plan and co-ordinated with similar research in England and in Australia.

The Pharmacy Industry

The Minister of Industries and Commerce in the Labour Government has provided a plan for the reorganization and control of pharmacies in accordance with the advice of the Bureau of Industry. This plan has been submitted to the principals of more than six hundred

pharmacies in New Zealand, who must vote on the question. The basic points have been outlined as follows: ensuring the dispensing of standard quality drugs at reasonable prices by, or under the immediate supervision of, qualified pharmacists; retaining individual ownership and operation of pharmacies without preventing the properly controlled operation of company pharmacies with branch shops; the exclusion of wholesale druggists, manufacturing chemists, and oversea representatives whose industries may be the subject of separate plans. The Minister stated that "the plan does not propose to introduce at the present stage an official drug tariff and a standard dispensing fee and to require their compulsory observance, but it is recognized that when practicable those steps should be taken." It is also proposed to appoint employees as members of the Pharmacy Board. The Pharmacy Plan Industrial Committee is to have three members nominated by the Government, two by the Pharmacy Board, one from friendly societies' dispensaries, and one from employees of pharmacists. The Director of Pharmacy is to be appointed subject to the approval of the Bureau of Industry. Certain immediate advantages which pharmacists may gain by way of protection against competition may induce a majority to vote for this form of control of their business by the "socialization" of the means of production, distribution, and exchange. If the pharmacists take the Government into their businesses they will not easily get rid of Government control if they so desire at a later period. What is good for the pharmacists may be considered good for medical practitioners, so that the medical profession cannot remain unconcerned about these novel and apparently drastic "plans."

Hydatid Disease

The number of cases of hydatid disease in public hospitals in New Zealand last year was 133; the number of patients in their own homes and in nursing homes is not known precisely, although the disease is notifiable. The mortality rate is 16 per cent. The Royal Australasian College of Surgeons has established a register of fully recorded cases, which now number over a thousand in the register. New legislation has just been passed in New Zealand amending the Dog Registration Act with the object of checking the spread of hydatid disease. The Minister of Health explained to Parliament that the cycle of the disease from the sheep to the dog and from the dog to man was well known. The only certain remedy, he said, was for people to give up feeding raw livers and lights to dogs. Compulsion in this matter was not possible, but education of the public might be gradually effective. The amendment to the Act, however, provided the next best thing, and ordered a form of treatment which had proved useful in the Argentine, Nicaragua, and Iceland. In future, when dogs are registered the owners will be compelled to purchase arecoline hydrobromide and give this to the dogs at regular intervals as a vermicide. At the Royal Agricultural Show the Governor-General, Viscount Galway, called attention to the menace of hydatid disease, and made a special appeal to the farmers. There is no reason why, with proper supervision and the imposition, if necessary, of penalties, this disease cannot be completely eliminated from the country.

The following awards have been made to medical men from the fund placed at the disposal of the Secretary of State for the Colonies by the Trustees of the Carnegie Corporation for the purpose of enabling selected officers of the Colonial Service to undertake special courses of study: Dr. C. J. Austin (medical superintendent, Central Leper Station, Makongai, Fiji), for the study of leprosy in Egypt, India, Malaya, and the Philippine Islands; Dr. W. B. R. Jones (medical officer, Nevis, Leeward Islands), for a course in general surgery at the University of Edinburgh; Dr. A. H. Lowther (Malayan Medical Service), for studies in ophthalmology in Europe, India, and Egypt.

abundantly proved that a pasteurizing temperature much lower than 145° F. will be sufficient to ensure an entire freedom from tubercle bacilli. I am wondering how Dr. Macfadyen can excuse the presence of abortus organisms in certified milk.

Over a long series of investigations in the United Dairies laboratories 70 per cent. of herd samples of certified milk contained the abortus organisms of undulant fever. Of the same samples 63 per cent. contained the haemolytic streptococci of mastitis. I do not think anyone will suggest that the ordinary acid- and gas-forming organisms which are all included under the heading of *B. coli* are in any way comparable in their deleterious effects to these two organisms, *B. abortus* and the *Streptococcus haemolyticus*. The emphasis placed by certified milk producers on the gross bacterial plate count is not significant, since milk which has been pasteurized is entirely free from potential pathogenic organisms. A suggestion made in Dr. Macfadyen's letter that pasteurization is difficult to control is entirely unwarranted. The phosphatase test gives a complete control of the efficiency of pasteurization.

Dr. Macfadyen ends his letter by saying that "if a compulsory scheme were put into operation there would undoubtedly be a false sense of security." What alternative would he suggest? The only one I can see is that a standard of purity would be required that made it a penal offence to sell milk containing the bacillus of tubercle, *B. abortus*, and perhaps the mastitis streptococcus. Does Dr. Macfadyen demand a freedom to sell milk infected with these germs without penalty? Surely not. The United Dairies consistently apply a test of the bacterial content of pasteurized milk—namely, a plate count of milk samples, two days after bottling, taken from unsold supplies returned from the rounds. Two days is generally the longest period of storage of milk in homes. The results are convincing, and abundantly prove the efficiency of pasteurization. There is no question but that pasteurization is the only process which will ensure a supply of safe milk for public consumption.—I am, etc.,

London, S.W.16, Jan. 26.

JAMES KIRKLAND.

Recovery in the Spinal Cord

SIR,—In the dissecting room and at surgical operations students are taught to preserve the nerves but to ignore the small blood vessels; this teaching, however, must not be generalized to the central nervous system. Mott's experiment (quoted in my paper in this issue) demonstrates the dependence of cord function upon the blood supply, and therefore a meticulous conservation of the small vessels is of primary importance in all operations upon the central nervous system.

The report of Dr. J. Purdon Martin's paper in the *Journal* of December 18 (p. 1242) includes in the consideration of requirements for recovery: (a) "interference with its circulation," (b) "scarring," and (c) subsequent "nutritive" of the cord; these are, however, subordinated to (a) severe cord damage, (b) glial overgrowth, and (c) provision of nutrient substances, respectively. The relation of the unfavourable prognosis of local syphilitic lesions and of intercurrent or chronic infections to vascular defect also is not made clear. Recovery of function in the cord is primarily dependent upon the restoration of blood supply to ischaemic areas.—I am, etc.,

F. A. PICKWORTH.

Director, Joint Board of Research
for Mental Disease.

Northfield, Birmingham,
Jan. 29.

Acute Appendicitis

SIR,—May I draw your attention to a point made in Dr. A. M. Spencer's interesting article (*Journal*, January 29, p. 227) on the aetiology of acute appendicitis? I refer to a sentence in the paragraph headed "National Distribution," which states that "in the villages of India and China the disease is unknown." This statement is an important, though perhaps not essential, link in his argument, and therefore deserves some comment. I believe that it has found its place in contemporary literature partly, at any rate, as the result of a paper by Weischer of Tsingtao, and I have seen this source many times referred to and copied.

I do not know anything about India, but it is true that appendicitis is not a common emergency in Chinese practice. It does not, however, follow that because cases of acute appendicitis are not often brought into hospitals, which are nearly always situated in towns, it does not exist in the villages. The large majority of Chinese peasants who come to hospital do so for economic reasons—they cannot do their work. In the mind of the Chinese peasant very few, if any, diseases are acute and require immediate intervention; the local resources must first be exhausted, and by that time the patient has either recovered or died.

The incidence of acute appendicitis in a well-established hospital increases slowly with a local realization of its gravity. Students who go home to their villages tell stories of patients with histories which are unmistakable, and needle marks in the right iliac fossa are common enough. This is the result of "needling", universally used to produce counter-irritation. I have more than once opened an abdomen to remove an appendix and found the caecum adherent to the anterior abdominal wall at the site of an old needle scar. Further, the incidence of appendicitis among a large student community eating Chinese food is, I think, about the same as that among the foreigners eating foreign food. Similarly, it was commonly said that tabes dorsalis and epidemic encephalitis did not occur in China. When the late Dr. Andrew Woods, neurologist to the Pekin Union Medical College, went out into the country to look for it he found a considerable number of cases.

The incidence of disease in China and other village communities is undoubtedly difficult to estimate, but there exists enough evidence to show that negative propositions such as the one to which I refer are based on incorrect information, though they may or may not be partially true.—I am, etc.,

H. W. S. WRIGHT,

Late Associate Professor of Surgery,
Cheeloo University, Tsinanfu.

London, W.1, Jan. 28.

Correct Footwear

SIR,—I should like to endorse Dr. Dorothy E. Mason's contentions regarding the requirements of the normal female foot (*Journal*, January 22, p. 203). In my student days Mr. E. K. Martin was able satisfactorily to demonstrate that "heels" were quite unnecessary. And ultimately a well-known London firm of shoemakers has been able to show that a "heel-less footprint shoe" need be neither spatulate, ungulate, nor rectangular, needing only to fit like a glove round the instep and heel and to leave the toes room to exercise. (An objection to heel-less shoes is commonly based on experience of the bedroom slipper—a sloppy object.) Elegant materials and craftsmanship can undoubtedly do much to mask any unorthodoxy. By taking weight off the toes and distributing it

Rehabilitation Necessary.—A complete recovery and the return to original employment is possible, if careful and expert treatment is followed by expert rehabilitation, in 25 per cent. of cases.

Vocational Retraining Necessary.—Even with the best treatment the patient will be permanently incapacitated from his work, and he must therefore learn a new trade, in 5 per cent. of cases.

There are two sources of permanent incapacity after bone and joint injury: (1) pathological changes over which the surgeon has little or no control, such as deprivation of blood supply of the articular cartilage of the carpal bones, head of the femur, astragalus, etc.; irreparable damage to the main vessels or nerves of the limb; and virulent infection beyond the control of conservative surgery; and (2) malunion due to imperfect reduction or redisplacement; non-union due to inadequate immobilization; joint stiffness due to injudicious splinting, passive stretching, continuous skeletal traction, etc. In the first group permanent incapacity is inevitable, but the proportion of cases in most fracture clinics is less than 5 per cent. The figure will obviously vary in different centres according to the relative number of major and minor injuries treated, but in the average city hospital in industrial areas the proportion should be within 5 per cent. In the second group permanent incapacity is not inevitable: it is the result of an avoidable error of treatment, and in past years this has been the most common source of disability, in some cases the figure for permanent incapacity in this second group approaching even 20 or 30 per cent.

That it is already inconceivable that treatment could ever have been so bad is a great tribute to the British Medical Association Fracture Committee, and to those few individuals who for many years have worked incessantly to improve the standard of fracture treatment in this country. But the goal is not yet reached, nor will it be attained by the establishment of fracture clinics alone. The success of the clinics will be judged by the extent to which they minimize the avoidable errors of treatment. The surgeon who adopts haphazard methods, who ignores radiographic control of treatment, who accepts indifferent methods of immobilization, and who blames his end-results on the fracture or the patient instead of on the treatment, will always find it difficult to believe that disability is inevitable in only 5 per cent. of injuries. When surgeons in charge adopt the principles of fracture treatment whole-heartedly, exercising the utmost vigilance, allowing no complication to pass unrecognized and uncontrolled, and inspiring every patient with enthusiasm, only then will avoidable incapacities be avoided. Unless this is done the rehabilitation centres, which we are determined to establish, will be faced with the same impossible task as the old massage departments.—I am, etc.,

Liverpool, Jan. 25.

R. WATSON-JONES.

SIR,—Mr. Eastwood's letter in the *Journal* of January 22 (p. 202) is indeed timely, and raises many important issues on this subject. Nobody would seriously maintain that the percentage of incapacitated persons leaving a fracture clinic is as low as 5 per cent., nor is there the slightest hope that this figure can ever be remotely approached, let alone reduced. In all probability the fracture clinic figure of 5 per cent. mentioned in the memorandum of the Joint Committee of the British Medical Association and the Trades Union Congress is meant to suggest that this is the proportion of patients totally incapacitated by reason of fractures sustained during the course of their work. Even if this supposition is correct the figure is low, because there is no doubt that the

industrial accident is often a very mutilating affair. The insurance combine's figures of disability quoted in Mr. Eastwood's letter are not high, and undoubtedly include cases of permanent total incapacity and also permanent partial incapacity. It should be borne in mind that an apparently trivial accident, or a fracture, which leaves even a trace of impairment of function may, in a skilled workman, result in a permanent partial incapacity sufficient to prevent him from ever again working with the same degree of efficiency.

Mr. Eastwood is perfectly right in suggesting that before schemes for the establishment of these centres are embarked upon reliable statistics should be obtained from all sources: from surgeons treating large numbers of fractures, from insurance companies, trade unions, etc. There is every likelihood that the results of work done in rehabilitating the injured workman may be disappointing for those who will be forced to provide the means for setting up and maintaining the centres if our profession persists in talking of percentages of cures which never have been, and never will be, attainable by any system of treatment.

My personal view is that the sympathetic employer is the best rehabilitating agent, but with labour as cheap as it is to-day and the rate of production so accelerated, even after a course of treatment at the best rehabilitation centre the maimed man, especially if he is getting on in years, will still have very great difficulty in resuming his place in the industrial scheme of things.—I am, etc.,

Manchester, Jan. 28.

HENRY POSTON, M.Ch.

Safe Milk

SIR,—May a sanatorium worker express thanks to the British Medical Association for coming into the open at last on the question of safe milk? Every year this country spends hundreds of thousands of pounds on "curing" tuberculosis or dealing with outbreaks of milk-borne disease. Its efforts to prevent such troubles are less spectacular, scientists being less clamant than agriculturists. Housewives who strive intelligently to do the best for their families have been befogged by conflicting opinions: "Doctors tell you such different things," they say. This has been true largely because doctors are insufficiently interested in public health problems, and they themselves have been blown about by diverse winds of doctrine. To the British Medical Association's considered opinion, however, widespread respect is accorded, and it means a great deal to crippledom that the Association should have spoken with no uncertain voice.—I am, etc.,

Berks and Bucks Joint Sanatorium,
Peppard Common, Oxon, Jan. 31.

ESTHER CARLING.

Pasteurization of Milk

SIR,—When dealing with such an important article of diet as milk one should be careful to be not only accurate but in a position to prove statements made. Dr. Norman Macfadyen's letter (January 15, p. 148) leads me to think that he is "boosting" certified milk in preference to pasteurized milk. He does not distinguish between *B. coli* of a non-faecal type and *B. coli* of manurial contamination. This is an important consideration, since the *B. coli* found in pasteurized milk are almost invariably of the non-faecal type. A distinction between these two types of *B. coli* is rarely made, and this omission leads to misunderstanding and a general idea that all types of *B. coli* are of manurial origin. So far as the effect of pasteurization on tubercle bacilli is concerned, it has been

Exercise may be painful, but it is necessary to break up and disperse fibrous masses.

It has been our aim to institute a routine for all forms of rheumatism which requires no expensive apparatus, medication, or medical supervision. In working out a routine treatment applicable to all rheumatic cases it has been our object to treat these unfortunates with the simple things, and the results, in our opinion, are worthy of record. A physician who waits until "the fire had burnt itself out and left only the charred remains in the form of distorted joints and twisted limbs" is failing in his duty to his patient. When the disease has reached that stage we tell patients that it is hopeless, and futile to waste their money in useless experiments. In rheumatism particularly, and in medicine generally, it is well to remember that

A little fire is quickly trodden out,
Which, being suffered, rivers cannot quench.

—I am, etc.,

Halcyon Springs, British
Columbia, Jan. 8.

F. E. BURNHAM,
Brigadier-General.

The Problem of the Final M.B., B.S.Lond.

SIR.—The letters which you have been printing concerning the final M.B., B.S. examination are anything but complimentary to the Royal Colleges, and it is time that someone protested against such remarks being made by men representing a University which gives its students no real university life and can persuade only three-quarters of them to sit for the final examination. It will be admitted by most teachers that students who intend to take the M.B., B.S. can do so if given sufficient time, and also that a fair number of those who take the conjoint examination could pass the M.B., B.S. The leaders of our Royal Colleges should realize that at least a third of their students want a so-called university degree and are quite capable of obtaining one if given the chance to do so. I know that they can sit for the Fellowship or Membership examinations, but both these are specialists' diplomas. Why do not the Colleges obtain power to grant an M.B., B.S. of their own, making the examination a severely practical one open to men whose names have been on the *Medical Register* for a year or more? The general public would soon learn that here at last was a degree which was based on practical knowledge and not on textbook theory.

Every winter I engage an assistant to help run my practice, and I have had a number of graduates of various universities. It is unusual to find one who can advise a patient about diet, or who can deal with a difficult labour, or write a prescription, dispense a bottle of medicine, or even open a septic finger. This is a sad commentary on the teaching they have received and the degrees they have obtained. Perhaps the preacher was right when he exclaimed that of the making of books there was no end and that much learning was a weariness to the flesh. Perhaps he had foreknowledge of the M.B., B.S.Lond. when he summed up with the words "Vanity of vanities, all is vanity."—I am, etc.,

Ipswich, Jan. 25. C. S. STADDON, M.R.C.S., L.R.C.P.

SIR.—I submit that it is desirable to put on record the history of this controversy before taking final leave of it. A proposal that "the University might accept for the purposes of part of the M.B., B.S. degree the results of the Conjoint Final examination" was submitted to the Faculty Board in a memorandum dated January 11, 1937, by the then Vice-Chancellor, Mr. Eason (the present

Principal), who stated that he had discussed this proposition "informally and unofficially" with the late Sir Edwin Deller, with Lord Dawson, with Dr. A. M. H. Gray, and with the then acting Principal. The memorandum may therefore be assumed to be the result of that joint effort, and Dr. Gray's chagrin at its failure becomes intelligible.

The motive given by the Vice-Chancellor for taking this action was the communication from the Court, quoted in my letter published on January 8, "with reference to the small number of students in medical schools who take a University degree." The Vice-Chancellor's argument for the proposed co-operation with the Conjoint Board was based upon certain figures in his memorandum, which were immediately demonstrated to be grotesquely erroneous. Many members of the Senate urged the desirability of having more precise knowledge of the facts before seeking outside advice, and a committee was appointed to investigate the present position. It is cheering to note from recently available figures that whereas the number of new candidates for the final Conjoint examination shows a considerable decrease—583 in 1936, 445 in 1937—the numbers graduating M.B., B.S.Lond. for the three years 1935, 1936, 1937, were respectively 144, 156, and 182—a progressive rise.

The Vice-Chancellor's memorandum was very carefully examined on February 23, 1937, at a full meeting of a subcommittee of the Faculty Board. The Dean of the Faculty of Medicine, who was chairman both of the Faculty Board and of the subcommittee, submitted a memorandum following closely the suggestions made in the Vice-Chancellor's memorandum but with somewhat more detail. A specific suggestion was made in the Dean's memorandum that a student having passed the final Conjoint Board examination and also the second M.B. examination should be granted exemption from the written papers of the final M.B., B.S. examination, but in order to qualify for the final M.B., B.S. should sit for a supplementary clinical examination three to six months after taking the final Conjoint Board examination. This memorandum also declared that "it is desirable that the M.B., B.S. examination should be held twice a year as at present": a suggestion that that examination should be held four times a year was met with the significant objection, to which I would invite Dr. Colyer's attention, that this action would constitute "competition" with the Colleges and therefore was not to be entertained.

The report of the subcommittee was submitted to a meeting of the Board of the Faculty of Medicine on March 4, 1937. Although the Court had clearly shown it was willing to wait for the improvement expected from the new curriculum, which could not be manifest for at least five years, the Faculty Board considered the matter to be of such extreme urgency that they proposed to discuss immediately and directly with representatives of the Royal Colleges the scheme outlined above. It was only upon my representation that it would be imprudent to take such action before consulting the Academic and External Councils and the Senate that the Faculty Board finally resolved to follow the constitutional course I advised.

Dr. Gray is not quite correct in his description of the action taken by the Faculty Board. While, as he says, the Faculty Board came to no decision with regard to the suggestions outlined above, their report to the Senate states that "they regard them" (that is, the suggestions) "as being of sufficient importance for discussion with the Royal Colleges, and they therefore make the recommendation set out below: That the Board of the Faculty

naturally, even long hours of walking are devoid of discomfort; and, having no height of heel to step over, it becomes possible to catch the departing bus without having to prance or scuttle. In a small boat, where the need for security of foothold is already generally recognized, no one would dream of wearing heels. Really good shoes are always expensive, but these I have mentioned are considerably cheaper than are bespoke shoes; they are also better fitting, probably because it is impossible to persuade even a good bespoke shoemaker completely to abandon the type of twisted last to which he is accustomed.—I am, etc.,

London, W.1, Jan. 26. ALISON MACBETH, M.B.Lond.

SIR,—The recent correspondence about correct footwear seems to me to be an attack on shoe manufacturers rather than a considered survey of the situation. In the first place people who have never worn shoes can develop valgus deformity of the toes and even bunions. I have in my possession several prints of the feet of African natives which prove this. Secondly, shoe manufacturers now but rarely make shoes with an extremely pointed toe. When I was collecting material from a shoe factory for a lecture two years ago I was able to find only one model the inner border of which deviated sufficiently from the straight to be of use for demonstration purposes.

Raising the height of the heel and putting a relatively rigid sole on the shoe has resulted in a lack of exercise of the toes, and this has been responsible for a great deal of the valgus deformity which is blamed on the shape of the inner border of the shoe. Many people in England wear shoes that are too short for them. This is the chief factor in the causation of deformed feet. Shoes should be made in a sufficient variety of widths to enable everybody to be fitted with footwear of the correct length. This is an expensive and difficult thing to do; it is achieved in America, but American shoes are appreciably more expensive to manufacture and to retail than are our own.—I am, etc.,

Street, Somerset, Jan. 27.

J. NEWMAN HEALES,

SIR,—I have followed with much interest the correspondence on correct footwear, and was especially interested in Dr. Dorothy Mason's letter in the *Journal* of January 22 (p. 203). I have been of the opinion for some time that the heel of a shoe is useless and a cause of much foot trouble. The heel originated as a *point d'appui* for the stirrup when riding. The only use that I can see for it is to provide a thicker part to reduce the wear at the point where most of the weight is taken by the shoe when walking. Now the heel, by displacing the centre of gravity of the body forward, causes a compensatory lordosis which the wearer retains during all his or her (especially her) periods of standing and walking. This cannot be anything but bad, and is in addition to the local damage to the foot. I have worn shoes without heels for about three years, and can testify to their very great comfort. I walk in them without fatigue, and am conscious while wearing them that the foot is working as a whole. Since taking to them my feet have developed such a flexibility that I can pick up a pencil with my toes with ease. These shoes are supplied by Messrs. Charles Baber, Ltd., 304, Regent Street, London, W.1, but they are unfortunately rather more expensive than ordinary shoes. Throughout the correspondence I have seen no allusion to the old type of open sandal; these are also to be had from Messrs. Baber, and are beautifully made. I have a pair, and during last summer I practically lived in them. They can be worn with or without socks,

and are delightful without. These seem to me to be the ideal footwear for the warmer weather, since there is nothing to constrict the feet and they have all the benefit of fresh air. Fresh air is inimical to the growth of fungi, which are a cause of much discomfort, sensory to the sufferer, and olfactory to others. Some might say that sandals fail to give support, but normal structures need no artificial support, and most feet would derive great benefit from the exercise that sandals would permit. Another objection is that they might cause the arches to fall, but has not the conception of flat-foot changed during recent years, and do not our orthopaedists tell us that the trouble with so many feet is that they will not flatten? Satisfactory sandals are also made by Messrs. Clark of Street, Somerset, at a very reasonable price; these can be obtained almost everywhere. There can be little objection to the wearing of sandals in these days when transport is easy and when the streets and roads are so clean and well kept. The subject of correct footwear is one of national importance, and in the drive for physical fitness the Ministry of Health should turn its attention to the correct shoeing of the population. A nation with bad feet cannot be fit.—I am, etc.,

Dartford, Kent, Jan. 23.

F. OLIVER WALKER.

Hydrotherapy for Rheumatoid Arthritis

SIR,—The report of the Health Resorts Conference at Bath contains extraordinary statements to which strong exception should be made. One speaker stated that "it was his considered opinion that no case of rheumatoid arthritis was suitable for a course of hydrological treatment so long as the slightest sign of activity still persisted." This is like waiting until a fire is well under way before sounding the alarm. To another speaker is accredited the statement that "no case of true rheumatoid arthritis in any active phase should ever be treated by hydrotherapy." Unless strongly contradicted these statements will destroy the last hope for thousands of patients. May I point out the treatment pursued at Halcyon Hot Springs, which has been the Mecca for rheumatics for fifty years.

Stretcher cases in the acute stage of rheumatism are immediately put into the pool, where they remain for twenty minutes. This is repeated from two to four times daily. Patients suffering from sciatica and other forms of neuritis may go in from eight to twelve times in the twenty-four hours. One speaker at the conference recommended "a depth of water of about 2½ feet and a temperature of between 99° and 100° F." The pools at Halcyon are 5 ft. deep, and large enough for swimming and exercise, which is insisted upon from the beginning. The temperature of the men's pool is 106°–108° F., and the women's pool is 102° F. These are the temperatures which have been found by experience to be the most effective.

All forms of rheumatism receive the same treatment. For, after all, rheumatoid arthritis is the severe form—the last stage—of the general disease. Every attack of rheumatism, however mild, is treated as a potential case of rheumatoid arthritis, and treated as such from the beginning. Exercise is necessary to maintain the joints in normal physiological activity. A strong indisposition to take exercise is a feature of rheumatoid arthritis which is the cause of endless trouble. Without exercise favourable results are impossible. Patients do better with a physician of the military type who manhandles his patients rather than the fawning type which hears and heeds every whim and fancy. Exercise is firmly insisted upon, and the direful result of neglect is clearly pointed out. We accept no excuses. Daily exercise is directed to stretch altered fibrous tissues and accustom them to movement.

Obituary

SIR JAMES CRICHTON-BROWNE, M.D.,
LL.D., D.Sc., F.R.S.

Formerly Lord Chancellor's Visitor in Lunacy

We deeply regret to announce the death at Dumfries on January 31 of Sir James Crichton-Browne at the advanced age of 97. In his passing from our midst, not only does psychiatry lose an honoured and distinguished leader, but the profession as a whole mourns the loss of an illustrious physician and a wise counsellor and friend. His venerable and commanding presence; the charm of his manner and the richness and force of his oratory; his clinical acumen and his practical sagacity; his unflagging interest in all that appertained to the world of medicine and of literature; and his great goodheartedness, rendered him alike a unique and unforgettable figure in the annals of contemporary medicine.

James Crichton-Browne was born on November 29, 1840, at St. John's Hill, Edinburgh. His father, Dr. W. A. F. Browne, Commissioner in Lunacy in Scotland, had been the first medical superintendent of the Crichton Royal Institution, Dumfries, and was not only an eminent psychiatrist—he was President of the Medico-Psychological Association in 1866—but a man of wide culture and of high scientific attainment. His mother also was highly gifted. Few knew their Shakespeare and their Burns as she did; and fortunate in the possession of an exceptionally good memory, she was in the habit of reciting to her son by heart whole passages with whose beauty she was desirous of impressing him. Many eminent men of letters—Dr. John Brown among others—used to foregather at their table; and thus it was that the son came early to nourish that love of literature and rhetorical skill which later he was to put to so good a use. Educated at Dumfries Academy, and later at Glenalmond, Crichton-Browne entered the University of Edinburgh at the age of 17. It is interesting to note, as witnessing his early bent towards matters psychological, that while still a student he read before the Royal Medical Society a paper entitled "Psychical Diseases of Early Life." He qualified L.R.C.S.Ed. in 1861, and took the M.D., with honours, in 1862. He was elected by his fellow-students President of the Royal Medical Society.

On graduation his interests in cerebral physiology and in psychology were already declared; and his apprenticeship in the study of mental medicine was served successively in the County Asylums of Derby, of Devon, and of Warwick. In 1865 he was appointed superintendent of Newcastle City Asylum, which post he relinquished to become medical director of the West Riding Asylum at Wakefield. There he instigated work which exerted a profound influence upon the development of psychiatry and neurology in this country. At the outset he recog-

nized that, while there was abundant material for investigation in asylums, there were but few facilities for medical officers to undertake research work. He recognized, moreover, that the failure to produce such work was partly due to the absence of any stimulus to the arrangement and elaboration of the material collected, and to the want of a channel of exposition. It was with a view to supplying this deficiency, and of affording an incentive to the utilization of much valuable information buried in case-books, that he projected the *West Riding Asylum Reports*, the early volumes of which have now become psychiatric classics. The first of the series was published in 1871. Crichton-Browne established at Wakefield the first neurological research laboratory in the Kingdom, where Sir David Ferrier was enabled to carry out his experiments on cerebral localization. The *Reports* contain the results of these experiments, as well as many other contributions from Hughlings Jackson, Clifford Allbutt—at that time a physician at Leeds Infirmary—Lauder Brunton, William Turner, and Bevan Lewis, then a medical officer at the asylum and later medical director. For a time Wakefield Asylum was the centre of neurological interest, and many eminent men congregated there and made their contributions at the monthly medical conversaziones which were organized at that institution by its director. The pioneer work thus begun has had far-reaching results, and so far as Wakefield itself is concerned the tradition for research set up by Crichton-Browne has been ably upheld by his distinguished successors, Herbert Major, Bevan Lewis, and Joseph Shaw Bolton.

In 1875 Crichton-Browne was appointed Lord Chancellor's Visitor in Lunacy. Everywhere the appointment was recognized as a fitting tribute to his energy and genius in the study of insanity. To commemorate the occasion a complimentary banquet was held, presided over by Lord Houghton, and fitting acknowledgments were made of Crichton-Browne's arduous labours at the West Riding Asylum and his enthusiasm for lunacy reform. Some two years later he sat with Dr. Hughlings Jackson, Sir John Bucknill, and Sir David Ferrier as member of a committee to consider the establishment of a special journal devoted to neurological research. The following year saw the foundation of *Brain*, which, in spite of many early vicissitudes, lived to uphold the traditions of British neurology and to become later, under the aegis of Hughlings Jackson, the official organ of the Neurological Society, and to occupy, as it still does, a high position in medical literature. Of this journal Crichton-Browne was co-editor. Among his contributions were articles on "The Weight of the Brain and its Component Parts in the Insane" and on "The Nature and Cortical Localization of Muscular Sense."

He was elected President of the Medico-Psychological Association in 1878. His address on this occasion, in which he reviewed the recent developments in psychiatric knowledge, was a striking illustration of his imaginative power and his felicity of diction. In the following year

of Medicine be authorized to discuss with representatives of the Royal College of Physicians and the Royal College of Surgeons the possibility of devising an alternative mode of approach to the M.B., B.S. degrees."

This recommendation met with a rough passage at the Academic and the External Councils, and subsequently at the meeting of the Senate on May 19, 1937. All that the latter body would sanction was "that the Board of the Faculty of Medicine be authorized to discuss with representatives of the Royal College of Physicians and the Royal College of Surgeons the problem submitted to the Senate by the Court—namely, the small number of students in medical schools who take a degree of the University of London." It is significant that whereas in March, 1937, the Faculty Board was in such haste to enter into negotiations with the Colleges that it was ready to commit the blunder of side-tracking the Senate, when the scheme met with the discouragement indicated by the Senate's variation of the Faculty Board's recommendation the Board suddenly lost interest in the matter. Although it was authorized as long ago as May, 1937, to consult with the Royal Colleges no effort to do so has yet been made. Dr. Gray is again inaccurate in his statement concerning my action with regard to the University of London Bill. That Bill became an Act in 1926, not 1927. It is true that I opposed the second reading of that Bill without, however, pressing my opposition to a division. But certain assurances given during the debate by the Chairman of the Departmental Committee which had prepared the Bill, and later, and still more authoritative, assurances given during the committee stage by the Minister in charge of the Bill, prevailed with me in accepting in committee the new position created by these assurances, and I received the thanks of the Minister. Moreover, I refrained from opposing the third reading. I have, not, however, concealed my regret at certain results of the Act, notably the removal from the Senate of the representatives of the London County Council and of the Inns of Court, bodies which had sent to the Senate many outstanding personalities, among whom may be mentioned Sidney Webb, W. J. Collins, Gilbert Warburg (L.C.C.); Moulton, McNaghten, Swinfen-Eady, Russell, McCall, Cozens-Hardy, Atkin, Tomlin. Their elimination is not, I submit, compensated, in the opinion of the great majority of the Senate, by the addition of the Deans.—I am, etc.,

House of Commons, Feb. 1.

E. GRAHAM-LITTLE.

Time for Midwifery

SIR,—A Sunday newspaper has recently published an article on maternal mortality. It was a good article, and said in effect: "It is a year since the maternal mortality report was issued: why has nothing been done?" The public have very good reason for dissatisfaction. The maternal mortality report, 1937, tells us that many women are killed and many more terribly injured in their confinements without due cause, and it sums up the situation very well on page 193: "When due allowance is made for maternal deaths which cannot be averted the fact remains that the present position of midwifery practice in this country cannot be viewed with equanimity." This is no exaggeration; this is true and admitted to be true by all men of honest minds.

Failed forceps cases are still being admitted to our maternity hospitals and cases of eclampsia are not unknown. Gas-and-air analgesia has been in use with great success in some hospitals for over four years, yet I find that in many districts within a hundred miles of

London no serious attempt whatever is being made to make gas and air available for all women. We must face the fact that, as the report says, "inexpert midwifery is a factor of major importance." There is one basic reason for inexpert midwifery and one reason only—want of time.

Since the introduction of the National Health Insurance Act the insurance practitioner with even a moderate panel finds, so great are the demands made on his services, that he simply has not got the time to give to midwifery. There is a solution of our difficulties—a full-time maternity service—and there is no reason why this should not be immediately established on a voluntary basis. In nearly all districts now there are women practitioners, and as women doctors seem to have a special aptitude for midwifery we should say to our women colleagues: "We intend to send you all our midwifery cases, and we shall ask you to respond to the midwives' call for medical aid." Soon they would be doing nothing but maternity work, greatly to the benefit of the patients.

If the medical profession had been willing to co-operate with Mr. Lloyd George we should have obtained a satisfactory National Health Insurance Act, so let us be warned by the fate which overcame us in the past and before it is too late build up a maternity service which will be a credit to our profession.—I am, etc.,

New Barnet, Jan. 28.

JOHN ELAM.

The Radiologist's Range of Service

SIR,—Once again the question of ownership of x-ray negatives has aroused much interest and comment. I am not so much concerned with this problem as with the implications contained in the following sentence from Dr. C. H. C. Dalton's letter (*Journal*, January 22, p. 206): "Every specialist of experience acquires a reasonable knowledge of the work carried out by those of his colleagues with whom he associates, and I am constantly called upon by medical practitioners, particularly in the country, to decide whether or not a bony injury requires the services of a surgeon." (Italics mine.)

All fractures require treatment, and the appropriate treatment for any individual fracture can be determined only by the experienced surgeon who has before him all the facts, clinical and radiological. Years of observation of combined clinical and x-ray results enable him to advise: "This fracture requires reduction"; or: "This fracture will give a perfect result with splintage only if a certain programme be followed," and so on. But a radiologist has neither the special training nor the wide experience which enables him to speak with authority on clinical end-results; and he has no responsibility for the welfare of the patient. Thus it is quite unfair to him and to the patient that he should be asked to express any opinion on the treatment of a fracture. I believe that a radiologist is entitled merely to report the presence or absence of fracture, and the presence or absence of displacement. His position does not entitle him to do more—certainly not to deny the patient the benefit of competent surgical advice.—I am, etc.,

Manchester, Jan. 31.

H. OSMOND CLARKE.

It has been announced in the *Yorkshire Post* that a proposal is under consideration for the provision in Leeds of a new radium institute to meet the needs of the West Riding. The scheme has been put forward by the West Riding County Council, the Leeds City Council, the General Infirmary at Leeds, and the Yorkshire Council of the British Empire Cancer Campaign.

beriberi. The identification of mosquito larvae has become such a matter of course in malaria surveys that his pioneer work in this connexion is almost forgotten, but without it the difficulties of anti-malaria work in the Malay States would have been insuperable.

Almost the whole of the European staff of the Institute was seconded for war service, and Stanton was left to carry on in Malaya. His wisdom and efficiency, his readiness to help, his steadiness and his cheerfulness were of untold value during the years of the war, not only to the Government but to the whole community. In 1917 he investigated a fatal disease which had appeared among the labourers on rubber estates and was causing some alarm among the public. The outbreak was thought at first to be the result of toddy poisoning, but Stanton showed that it was due to infection with the organisms of a glanders-like disease, which he afterwards named melioidosis. His work on this subject was published in conjunction with Dr. William Fletcher. In 1920 he was appointed Director of Government Laboratories in the Malay States. His wisdom and good judgment led all to seek his advice in every kind of difficulty; those who asked never asked in vain, but received strength and good guidance at his hands and left him feeling better armed to face their troubles.

In 1926 Stanton was chosen by the Secretary of State for the Colonies for the newly created post of Chief Medical Adviser in the Colonial Office. His admirable work in this capacity was recognized far and wide, and the present Secretary of State invited him to continue for a further period of three years from April next. He was created C.M.G. in 1929 and K.C.M.G. in June, 1934. The Royal College of Physicians elected him a Fellow in 1926 and awarded him the Bisset Hawkins medal. In 1911 he was awarded the Craigs Research Prize of the London School of Tropical Medicine, and in 1929 the Mary Kingsley Memorial Medal of the Liverpool School of Tropical Medicine. When his old University of Toronto conferred on him the honorary degree of D.Sc. in 1933 Stanton was delighted, and no other distinction he gained during his life gave him more pleasure than this.

Part of Stanton's duties at the Colonial Office was to act as a liaison officer between the Department and various medical bodies outside, and this, from his sound sense of judgment, he was particularly fitted to do. He was chairman of the Colonial Advisory Medical Committee and of the managing committee of the Bureau of Hygiene and Tropical Diseases. He was a member of the board of management of the London School of Hygiene and Tropical Medicine, of the Tropical Medical Research Committee, of the Medical Research Council, and of the British Empire Leprosy Relief Association. He was responsible for advising the Secretary of State on the numerous medical problems that require solution in the fifty or so Crown Colonies, each with its separate government and financial problems. During his tenure of office great progress was made in the medical services of these Colonies. In recent years it has been realized that deficient nutrition was responsible for a great deal of the ill-health of the native peoples of our possessions, and he took an active part in the formation of the Economic Advisory Council Committee on Nutrition in the Colonial Empire. He believed firmly that the welfare of the inhabitants of these territories was dependent on the co-ordination of the medical, agricultural, veterinary, and educational departments, and took active steps to ensure this. Every medical officer in the Colonial Medical Service regarded him as a personal friend, and was always

assured of a welcome in his office on arrival home on leave. They realized how much he always did for them in various ways and how much he has done to promote the health and welfare of millions of people in the Colonial Empire by bringing up the standard of its medical services by quietly fighting innumerable and often very difficult and worrying battles.

In 1930 he married Dr. Elizabeth O'Flynn, M.R.C.P., who survives him. The funeral took place at Golders Green on January 27.

[The photograph reproduced is by Elliott and Fry, Ltd.]

E. J. TOYE, M.D., B.Sc., F.R.C.S.

After forty years of busy life in practice at Bideford, North Devon, Dr. Edwin Josiah Toye passed away on January 25 after a very brief illness. He had a brilliant career at St. Bartholomew's Hospital, taking his B.Sc. in 1892, with honours in physiology, obtaining both the junior and senior scholarships, the gold medal for obstetrics in the M.B., and being adjudged worthy of the gold medal in the B.S. He was ophthalmic house-surgeon under Mr. Vernon and then for a year house-physician at the Metropolitan Hospital. In 1898 he took a locumtenency at Bideford with Drs. Rouse and Gooding. He became Dr. Gooding's assistant after Dr. Rouse's death and later his partner and successor. He struggled single-handed during the war with a growing practice, and later was joined in partnership, first by Dr. C. W. Wilson and then also by Dr. S. C. Wake.

In addition to his routine general practice Toye always maintained his interest in eyes, and was ophthalmic surgeon to the Bideford Hospital, in which he was also senior medical officer for many years up to the day of his death. He also held many posts of responsibility and honour among his colleagues. He was at different times president of the South-Western Branch of the British Medical Association, chairman of the Barnstaple Division, and later president of the Devon and Exeter Medico-Chirurgical Society, and for many years a representative of his Division in the Representative Body of the British Medical Association. He also took part in municipal work, and in 1925 served as mayor of Bideford. During his year of office the famous Bideford Bridge was rebuilt, and Toye's name will go down to posterity engraved on its memorial stone. In the same year the new Bideford and District Hospital was opened. In 1903 he married a widow, Mrs. Keene, who had three children, and he proved himself a devoted husband and stepfather. Mrs. Toye died in 1933. The great and representative congregation which attended his funeral at Bideford Parish Church on January 28 testified to the immense respect and affection in which he was held.

Mr. E. W. Hey Groves writes:

Dr. Toye was my oldest and dearest medical friend. We entered St. Bartholomew's Hospital together in 1890, qualified in the same year, held resident appointments at the same time—he as ophthalmic and I as obstetric house-surgeon—and we have been closely associated in practice in the West of England ever since. It was in 1898, when I was in general practice in Chewton Mendip, that Toye came to stay with me; he then heard of a post at Bideford as a locumtenent, and there he has been in practice ever since. For the last forty years we have met every year, and generally I have gone down to stay with or near him, and have had the pleasure of seeing him

his services to science and to the community were recognized by the University of St. Andrews in conferring on him the degree of LL.D. As President of the Psychological Section of the British Medical Association Meeting at Cambridge in 1880 he delivered an address "A Plea for the Minute Study of Mania," in which he pleaded for a more assiduous study of symptoms in the light of the recently acquired knowledge of cerebral pathology, and expressed the belief that it would be possible eventually to define in cases of insanity the particular parts of the brain involved. In 1884 Crichton-Browne submitted a report on the alleged over-pressure of work in public elementary schools concerning which public interest had been considerably aroused. Mr. Mundella, the Minister for Education, had not anticipated its nature, but the report was deemed so valuable that the House of Commons ordered it to be printed. When in 1886 the honour of knighthood was bestowed on him by Queen Victoria there was widespread satisfaction, both among the medical profession and the general public. At the British Medical Association Meeting at Leeds in 1889 Crichton-Browne gave an address in psychology on "The Hygienic Uses of the Imagination"—a subject affording full scope to his imaginative and literary powers. In that address he argued strenuously for the adoption of measures for the early treatment of mental disorders, and for the wider dissemination among the profession of a knowledge of medical psychology.

"But if the treatment of insanity in its earlier stages—when it is in the green tree and more amenable to control than in the dry—thus devolves on general medical practitioners, and if the management of a considerable proportion of cases of insanity throughout their entire duration is entrusted to them, with or without specialistic assistance, it follows obviously that the study of medical psychology appertains to our profession as a whole and cannot be altogether relegated to any one small branch of it."

It is not possible to do justice here to his multifarious activities in the realm of medical psychology. His services were in constant request both by specialist societies and by the general public. Sir James Crichton-Browne was treasurer and later vice-president of the Royal Institution of Great Britain; chairman of the Council of the National Health Society; a former president of the Neurological Society and of the Medical Society of London. He was elected a Fellow of the Royal Society in 1883. The degree of Doctor of Science was bestowed on him by the University of Leeds and the LL.D. by Aberdeen and Edinburgh.

In 1922 he retired from the office of Lord Chancellor's Visitor in Lunacy, but happily continued to maintain his interest in medicine and in psychology, and to continue his activities in lecturing on these and allied subjects to audiences in various parts of the Kingdom. In 1926 he resigned the treasurership of the Royal Institution after holding it for thirty-seven years with conspicuous success. He had been a member of the Athenaeum for forty-five years, and of the British Medical Association for seventy years. At the age of 89 he unveiled the memorial bas-relief portrait of his old friend Sir Clifford Allbutt in the Cambridge Medical School, and spoke with unabated point and vigour. The centenary celebrations of the British Medical Association in 1932 were graced by a letter from his pen in the *British Medical Journal*, conveying congratulations and good wishes; in this Sir James referred to "the adolescent period in the life of the Association, the seventies and eighties of last century, when I took an active part in its affairs," and paid charming tributes to the work of Ernest Hart, Sir Dawson Williams (Editors of this *Journal*), and their successor.

Sir James Crichton-Browne was twice married. By his first wife, Emily, daughter of the late Dr. Halliday, he had two children, a son and a daughter; the former died last October. His first wife died in 1903, and in 1912 he married Audrey Emily, daughter of the late General Sir E. Bulwer and great-niece of Bulwer Lytton. Mr. Balfour Browne, K.C., the Parliamentary Counsel, was his younger brother, and his nephew is Professor Frank Balfour Browne, president of the Royal Microscopical Society.

SIR THOMAS STANTON, K.C.M.G., M.D., F.R.C.P.

Chief Medical Adviser to the Secretary of State for the Colonies

Sir (Ambrose) Thomas Stanton, who died in London on January 25 after a short illness, was born in Canada on November 14, 1875, and graduated M.D. from Trinity Medical College, Toronto, in 1899. After serving as house-surgeon at the Toronto General Hospital he continued his medical studies in London—at University College and the London Hospital—obtaining the English Conjoint qualifications in 1905 and the D.T.M. and H. of Cambridge in the following year. At the Hospital for Tropical Diseases he acted as house-surgeon to Sir Patrick Manson, and afterwards was registrar. Sir Patrick chose him for the post of demonstrator at the London School of Tropical Medicine in 1905.

Stanton went to the Malay States in the beginning of 1907 to assist Henry Fraser, the director of the Institute for Medical Research at Kuala Lumpur, in an attempt to discover the cause of beriberi. Their earliest observations were made on two groups of coolies employed in building a road through virgin jungle. One of the groups was supplied with polished rice, the other—working some three miles distant—with parboiled rice. During this investigation Stanton lived for the best part of a year in a little thatched hut which stood in a clearing in the jungle at the dead end of the new road, many miles from civilization and its comforts. Here he kept a look out for cases of beriberi among the coolies, and dispatched daily specimens of their food sealed up in wooden boxes to Fraser in Kuala Lumpur. This remote spot, surrounded by high impenetrable jungle, was chosen to eliminate any question of infection, and because there was no opportunity in such a place for the coolies to obtain any food except that which was supplied to them. Stanton's life was terribly lonely and monotonous, but as a result of their observations Fraser and he were able to show that beriberi was a disease of metabolism due to the consumption of a staple diet of rice from which the outer layers had been removed by polishing. They found that these subpericarpal layers contained certain "alcohol-soluble substances, minute in amount but of high physiological value in nutrition," the substances to which Funk, a few years later, gave the name of vitamins. Stanton and Fraser continued their investigations into the prevention and cure of beriberi until the beginning of the war, and in 1924 their numerous papers on this disease were republished in one volume under the title of *Collected Papers on Beriberi*. Stanton was a keen entomologist, and his work on mosquitos was as valuable as his work on

argument or a friendly piece of advice with a "Do you follow me?" Much sympathy will be extended to his widow and six daughters, and to his son, Surgeon Lieutenant R. E. Lauder.

D. F.

JOHN ADAMS, F.R.C.S.

Mr. John Adams died at the age of 86, after a long illness, at his house in Aldersgate Street, E.C., where he had practised for over sixty years. His death removes an honoured and beloved figure from the City of London, where his professional skill and goodness of heart were known to citizens in every walk of life. His father, Richard Adams, was a yeoman farmer of Marlborough, near Salcombe, in South Devon, and throughout life John Adams, in manner, speech, and bearing, was the West Countryman exiled in London, yet loving the City almost as much as his native Devon. At St. Bartholomew's Hospital he was known as a first-rate student and house officer. He had qualified in 1872, and became F.R.C.S. Eng. in 1888. Settling in general practice in Aldersgate Street, he was appointed medical officer to the Royal General Dispensary in Bartholomew Close, and generations of Bart's men knew him as a frequent visitor to the wards, a sound diagnostician, and a kindly friend. He was elected a Governor of the hospital in 1904. During the war he served with the rank of colonel R.A.M.C.T. as honorary surgeon to the Hospital for Officers at Fishmongers' Hall. He was for many years surgeon to the Hospital of the Sisters of the Poor, Paul Street, and surgeon to St. Margaret's Hospital, Kentish Town. As senior surgeon to the Sheffield Street V.D. Hospital for Women, and more particularly as medical officer in charge of the Thavies Inn centre for pregnant women with venereal disease and their newborn children, Mr. Adams did invaluable work, throwing himself heart and soul into his duties there while carrying on a busy private practice. He recorded in the *Proceedings of the Royal Society of Medicine* and in *St. Bartholomew's Hospital Reports* the results of treatment of ante-natal and post-natal syphilis. In recognition of this work he received from the Hunterian Society a special centenary medal for research in general practice; he was also elected president of that society, and in 1920 chairman of the City Division of the British Medical Association, of which he had been a member for fifty-four years.

On January 18 (writes L. A. P.) there passed away at Brighton one of the best beloved of our doctors, ARNOLD WINKELRIED WILLIAMS, at the age of 74, after a long illness, which started last year on a visit to a married daughter in Canada. He received his medical education in Edinburgh, London, Hamburg, Prague, and Vienna, graduating M.B., C.M. with honours at Edinburgh University, and afterwards taking the D.P.H. He settled in Brighton as a dermatologist, and was appointed physician for skin diseases at the Royal Sussex County Hospital and at the Royal Alexander Hospital for Sick Children. Dr. Williams became vice-president of the Dermatological Section of the Royal Society of Medicine; he was also vice-president of the Section of Dermatology when the British Medical Association held its Annual Meeting at Brighton in 1913. He contributed many articles on his specialty to the medical journals. He was buried at Brighton, the funeral service being held at St. Mark's, Kemp Town. The Archdeacon of Westminster (Canon F. L. Donaldson) conducted the service, with the assistance of the vicar, the Rev. F. Keeling Scott. The service was attended by leading representatives of the local medical profession, and many of the officials and members of the committees of the hospital which he had served so faithfully and so long. Dr. Williams had a very charming

personality. It is difficult to imagine that he could have made an enemy. It can truly be said of him he was "beloved by all who knew him"—doctors, patients, friends. His colleagues in Brighton will miss an honest, upright, and learned English gentleman. He leaves a widow and three daughters.

The death of Dr. DAVID FAIRWEATHER on January 24 removes a practitioner long familiar to his patients and colleagues in the north of London. A graduate in arts (1876) and medicine (1879) of the University of Edinburgh he devoted himself from the outset to general practice, for the opportunities and responsibilities of which he cultivated a high regard, and he followed his profession effectively until some twelve months ago, when he elected to retire. He possessed in a high degree the qualities which invite and ensure confidence and obtained in a corresponding degree the affection and trust of his patients, while his standard of professional loyalty engaged the respect and goodwill of his colleagues. His personal interests included various public activities and sport in many forms, and he maintained his interest in the classics and had a rich fund of Scottish traditions and humour. His death means a loss to many circles to which he gave freely from the resources of his long experience and generous friendship. He had been a member of the British Medical Association for forty years.

After a short illness Mr. WILLIAM ALEXANDER MAIR died at Heckmondwike, Yorks., on January 10, at the early age of 39. A native of Port Knockie, Banffshire, he was a medical student at the University of Aberdeen, where he graduated M.B., Ch.B. in 1925. After two years as house-surgeon at the North Riding Infirmary, Middlesbrough, he held the post of medical superintendent of the Burnley Municipal Hospital until 1933, in which year he obtained the F.R.C.S. Ed. He then went into private practice at Heckmondwike, and two years ago was appointed honorary assistant aural surgeon to the Dewsbury Infirmary. Mr. Mair was also police surgeon at Heckmondwike and honorary surgeon to the local division of the St. John Ambulance and Nursing Association.

Dr. GUSTAVUS GEORGE GIDLEY died suddenly at Heyford House, Cullompton, Devon, on January 15. He was born at Gidleigh, Devon, in 1861, and from Queen's College, Taunton, went to King's College, London, and qualified as L.S.A. in 1885, taking the M.R.C.S. and L.R.C.P. diplomas in the following year. He was then in turn house-surgeon at the London Temperance Hospital, clinical assistant at the Royal Devon and Exeter Hospital, resident medical officer at the Morpeth Dispensary, and assistant medical officer at the Northumberland County Asylum. Dr. Gidley practised for a long time at Cullompton, and held various public appointments. He had been a member of the Exeter Division of the British Medical Association for twenty years, and was a past-president of the Devon and Exeter Medico-Chirurgical Society.

Dr. CHARLES HORACE ANDREWS, one of the best-known practitioners in Norwich, died on January 16, at the age of 76. A student of Edinburgh and St. Thomas's, Dr. Andrews took the Scottish triple qualification in 1891, and then indulged his love for foreign travel by serving as a ship surgeon and making several voyages to China, Japan, and the Cape. He took up practice in Norwich in 1895, becoming district medical officer and medical officer and public vaccinator for Norwich. He was also for some time surgeon and accoucheur to the Norwich Maternity Charity, and assistant medical officer and anaesthetist to the Norwich Workhouse Infirmary. His hobby was cycling, which he began in the "penny-farthing" days and continued for many years. He had been a member of the British Medical Association for forty-four years and took an active part in the work of the Division, holding office as chairman in 1922.

assume his rightful position as one of the most successful and most beloved of the practitioners in North Devon. He was the most conscientious and untiring worker, and although he has always had a cardiac lesion (which prevented his being accepted for military service during the war) he never spared himself in his devotion to his patients. He undertook the whole responsibility of a large general practice, and also kept up with his special ophthalmic work. His great knowledge and experience was fortified by constantly keeping in touch with modern progress, and right up to last year he hardly ever failed to go up to St. Bartholomew's for a postgraduate course. He was a pioneer in motoring, driving himself in a 4½-h.p. Benz in the early years of the century, and his own was the first car in North Devon.

Toye never learned to spare himself or to take recreation; his only holidays were the annual meetings of the British Medical Association. But he loved music, and I associate this with him from our student days when we attended Queen's Hall concerts to the last year when he came to Bristol to the opera with me. Our last close association was in 1935, when we travelled round the world on the B.M.A. tour. Toyé's was a character of singular charm. He was always absorbed in the interest of his work and yet he never complained of its drudgery. He was devoted to his patients and unsparing of himself in his work for them. He always seemed to be happy, and he thus made those associated with him happy, too. He was never bad-tempered, and I confidently believe that in all his long life he never made an enemy. His cheery smile, his leonine head covered with thick curly hair, and his brave spirit will long be remembered in the North Devon town which he had made his own.

W. B. MACKAY, C.M.G., M.D.

Consulting Surgeon, Berwick-on-Tweed Infirmary

By the death of Dr. William Bertie Mackay, C.M.G., Berwick-on-Tweed has lost its senior medical practitioner. He was born in Edinburgh in 1863 and studied medicine at the University of Edinburgh and at Charing Cross Hospital, graduating M.B., C.M.Ed. (with honours) in 1884, and taking the M.R.C.S.Eng. in the following year. After a period as resident surgeon at the Edinburgh Royal Infirmary he engaged in postgraduate study in Vienna, Heidelberg, and Paris, and began practice at Berwick in 1887. Dr. Mackay, who proceeded to the M.D. with commendation in 1896, had for many years been surgeon to the Berwick-on-Tweed Infirmary, and was prominently associated with the Territorial movement. During the war he was senior medical officer at the Command Depot, Catterick, and served with the British Expeditionary Force in France and Flanders, attaining the rank of Lieutenant-Colonel, R.A.M.C.(T.), and being thrice mentioned in dispatches. He received the Territorial Decoration, and was a Justice of the Peace for the county and borough of Berwick. He joined the British Medical Association in 1904, and was chairman of the North Northumberland Division in 1923-4.

Dr. R. A. Welsh writes:

Our profession in North Northumberland and Berwickshire has lost one of its best-known and best-loved members by the death of Dr. W. B. Mackay. He was a remarkable man, as his life's record shows: a fine type of general practitioner, a good general surgeon with a sound knowledge of ophthalmic work, an honours graduate of Edinburgh who had studied in London, Vienna, Paris, and elsewhere. Perhaps his greatest interest in life was

the development of Berwick Infirmary, where he laboured for over fifty years and was instrumental in building it up from a very primitive state to one of high efficiency. Apart from his profession his activities were manifold and various, as a short list of them will show. He had been president of the Rotary Club, the local branch of the British Legion, the Operatic Society, the Burns Club, and the Rugby football club. He was Sheriff of Berwick in 1925-6, and was made an Honorary Freeman of the town in recognition of distinguished war service. Forty-nine years ago he became an officer in the old Volunteers, afterwards the Territorials, and remained an officer till his death. Physically he was never robust, and suffered from heart trouble for many years, and underwent a serious abdominal operation not long before the war; but these disabilities did not deter him from joining up and going to France with the Northumberland Fusiliers in April, 1915. He had a distinguished war record, for two of his sons and a daughter also served over-seas. He was medical officer of his old battalion. During active service his health broke down, and he spent many months in hospital seriously ill, but his indomitable spirit and determination to get well carried him through. He got the C.M.G. for gallant service in 1916; was twice mentioned in dispatches, and made lieutenant-colonel in 1919. He returned to his private practice in Berwick and his hospital work, and carried on until six months before his death. He was an attractive personality. He had a cultured mind and a singularly gentle spirit. A striking characteristic was his great courtesy, which was the very essence of his being. Old and young, rich or poor, were all alike to him in this regard.

R. E. LAUDER, M.D., F.R.C.S.Ed.

Many men in the public health service will learn with regret of the passing of Robert Enwraight Lauder, which was announced last week at page 261. For over thirty years medical officer of health for Southampton, he played the chief part in the development of its medical services. He was always alive to recent advances and keen to adopt any measures which would further their application. This was evidenced by the very early introduction of an x-ray unit in the tuberculosis clinic, one of the first in the country. It was seen again in the eagerness with which he welcomed the Act of 1929, for he recognized that by it the local authority could extend its usefulness in the direction of hospital services. The same alertness was shown in every sphere of his administrative work, and the smoothness with which the whole was operated showed not only his mastery of detail but his ability to obtain that co-operation, both inside and outside a department, which is so necessary to success. He was held in high regard by his juniors, to whom he gave every help and encouragement. One other of his activities must be mentioned. He served in the South African War, 1899-1900, in command of a detachment he himself had raised, and on his return he was elected a Freeman of the Borough. At the beginning of the great war he found himself suddenly called upon to undertake many duties in addition to those of health. Much additional hospital accommodation in the area was necessary, and he found it, and from its inception he acted as colonel commandant of one of the large V.A.D. hospitals. During his active career he took a great interest in the work of the Southampton Medical Society and of the Southampton Division of the British Medical Association, and was an ex-president of both bodies. Lauder was a kindly man, and his old colleagues will remember with affection the low rumbling voice which usually ended an

of the Medical Faculty Buildings, Edmund Street, on February 17 and 24 and March 3, at 4 p.m. The first two lectures will be delivered by Sir Henry Dale, C.B.E., M.D., F.R.S., F.R.C.P., director of the National Institute for Medical Research, on February 17 and 24, and the third by Professor Francis R. Fraser, M.D., F.R.C.P., professor of medicine in the University of London and director of the Department of Medicine of the British Postgraduate Medical School, on March 3. Members of the medical profession and students of medicine are invited to attend.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

A Comitia of the Royal College of Physicians was held on January 27, with the President, Viscount Dawson of Penn, in the chair.

The following were elected representatives of the College: Dr. A. S. Barnes on the Court of Governors of the University of Birmingham; Dr. J. A. Nixon on the Court of the University of Bristol; Dr. A. Feiling on the Council of the Queen's Institute for District Nursing.

The following were appointed delegates: Dr. G. F. Buchan to the Congress of the Royal Sanitary Institute at Portsmouth, July 11 to 16; Dr. A. Ramsbottom to the Congress of the Royal Institute of Public Health at Blackpool, May 31 to June 4; Professor Roy S. Dobbins to the International Congress of Leprosy at Cairo, March 31; and Dr. J. D. Rolleston to the eleventh International Congress of the History of Medicine to be held at Zagreb, Belgrade, Sarajevo, and Ragusa, September 3 to 11.

Membership

The following candidates, having satisfied the Censors' Board, were admitted Members of the College:

Allan William Abramson, M.B.Camb., Cécile Helen Denise Asher, M.D.Lond., Harry Baker, M.B.Manch., Richard Erskine Bonham-Carter, M.B.Camb., Edward Aloysius Joseph Byrne, M.D.Bell., John Houghton Colebatch, M.D.Melb., Seymour Donald Mayneord Court, M.B.Birm., Samuel Barnett Dimson, M.D.Lond., James Findlay Dow, M.B.Camb., William Robert Macfarlane Drew, M.B.Sydney, Captain R.A.M.C., Tom Foulds, L.R.C.P., Thomas Bones Hamilton Haslett, M.D.Bell., James Holmes Hutchison, M.B.Glasg., Martin Cyril Gordon Israels, M.D.Manch., Byron Arnold Ryland Israels, M.D.Sydney, Robert Bews Kerr, M.D.Toronto, Abdel Hamid Mustapha Kersha, M.B.Cairo, Hah Long Lee, M.B.Hong Kong, Robert George Mallory Longridge, L.R.C.P., John Joseph McCann, M.B.Lond., Edward Rowland Alworth Merewether, M.D.Durh., Henry Francis Moore, M.D.Dubl., Noah Morris, M.D.Glasg., Alexander Jeremiah Orenstein, C.M.G., M.D.Jefferson Coll., Andrew Robertson, M.B.Ed., James Charles Shee, M.B.N.U.I., Horace Minton Shelley, F.R.F.P.S., Reginald Norman Tattersall, M.B.Lond., Prem Nath Wahi, M.D.Lucknow, Hugh John Wallace, L.R.C.P., Margaret Isabel Williams, M.B.Manch.

Licences and Diplomas

Licences to practise physic were conferred upon the following 159 candidates (including thirteen women) who had passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board, and have complied with the necessary by-laws:

H. Acton, C. L. Angell, M. G. Baker, W. H. J. Baker, R. E. Ball, A. D. Barnett, H. C. Barry, C. F. Barwell, A. D. Bateman, C. A. Bathfield, K. M. Bhansali, D. L. Bennett, J. R. Eignall, Joan M. Boissard, V. H. Bowles, W. E. W. Bridger, B. A. M. Brown, C. N. Brown, B. Browncombe, J. H. Bulleid, Jacqueline V. Burch, G. A. Burfield, P. E. G. Burnett, B. Burns, Elizabeth M. Cadbury, D. M. Carding, J. A. Chamberlain, I. C. Chopra, E. Clifford-Jones, S. Cohen, H. Cooper, T. A. Cox, R. V. Coxon, A. Crook, Dorothy L. Crossley, Eveline M. Cumming, S. S. Davidson, E. B. Davies, D. R. Davis, J. J. Davis, M. Dean, J. de Swiet, J. H. Dobree, A. S. Dods, E. G. Dolton, I. G. B. Drybrough-Smith, Avis M. Dyer, P. S. Edgecombe, A. M. Edwards, T. A. W. Edwards, P. G. Epps, C. C. Evill, A. C. Fergusson, J. O. Fielding, W. Fine, E. S. Foote, A. B. Fountain, J. E. Francis, B. J. Frankenberg, A. S. Garrett, P. F. B. Gillett, L. J. Grant, S. J. Green, P. R. B. Grimaldi, S. Grossmark, R. W. Gunderson, M. Halberstadter, J. W. Hallam, R. N. Herson, J. H. Hill, A. M. Hutton, Stella M. Instone, L. A. Ives, S. Jackson, E. L. James, P. H. Hayes, S. M. Jenner, E. C. Jones, James M. Jones, John M. Jones, R. C. Jones, B. A. R. D. Josef, M. Kaufman, J. W. L. Kemp, W. M. Kirkby, H. G. Langley, R. W. Lass, J. D. O'D. Lavertine, R. P. Lawson, A. S. Lee, J. B. Longmore, R. Lyons, J. Mackenzie, F. T. Madge, O. T. Mansfield, K. A. Marandi, Elizabeth C. Marshall, Mary O. Masters, S. W. Maxwell, O. Meerapfel, A. D. Messent, D. H. R. Montgomery, W. E. D. Moore, D. N. B. Morgan, J. N. Morrison, D. V. Morse, B. G. Neuhau, R. G. W. Ollerenshaw, P. J. O'Meara, T. Parkinson, J. N. M. Parry, C. Phillips, A. B. Pollard, K. W. Powell, D. W. Pugh, M. W. Radzan, L. Ray, M. T. Read, R. Rhyddwen, K. S. Richard, H. J. Richards, D. A. Richmond, J. W. Richmond, A. T. M. Roberts, C. A. Roberts, Mary A. Rogerson, E. Rosenberg, R. W. N. L. Ross, T. R. Savage, T. T. Schofield, J. W. Shannon, N. P. Shields,

G. L. B. A. Silva, G. H. A. Simmons, J. R. Sinton, F. M. Smith, H. D. Smith, K. Smith, H. W. Starkey, D. C. Sturdy, A. W. Taylor, K. H. Taylor, R. L. Thomas, A. H. Thomas, K. B. Thornton, A. G. G. Toomey, Ivy M. Tuck, Audrey V. Turner, W. M. L. Turner, N. Vere-Hodge, H. P. Watts, J. M. Wedderspoon, H. F. Whalley, T. E. Whitby, D. J. Wigginton, E. D. Williams, A. R. Wood, Jean R. Young, W. B. Young.

Diplomas in Psychological Medicine and Laryngology and Otolaryngology were conferred jointly with the Royal College of Surgeons of England. The names of the successful candidates were printed in the report of the meeting of the Council of the Royal College of Surgeons published in our issue of January 22 (p. 209).

Diplomas in Public Health were granted, jointly with the Royal College of Surgeons, to W. L. H. L. Bell, V. D.A. Blackburn, R. R. Clipstein, P. N. Gokhale, J. Landon, Caroline A. Meade, Gladys M. G. Spencer, Agnes B. Sutherland, Christina J. Thomson, Patricia S. Warren, J. O. Williams, V. F. F. Winslow.

Diplomas in Tropical Medicine and Hygiene were granted, jointly with the Royal College of Surgeons, to H. Prasad, B. M. Rao, A. C. Seneviratne, D. H. Waldron.

Diplomas in Anaesthetics were granted, jointly with the Royal College of Surgeons, to A. H. L. Baker, A. H. Bruce, Eva G. Byrde, J. C. Buckley, Bessie E. Cook, Ellen B. Cowan, M. H. A. Davison, A. J. S. De Freitas, L. M. De Silva, S. F. Durran, Florence Faulkner, W. B. Gough, G. Gray, J. R. G. Harris, J. K. Hasler, Ursula Y. Im Thurn, Freda C. Kelly, J. O. Moffat, D. A. Prothero, G. R. Rawlings, W. H. Scriven, Captain R.A.M.C., E. W. O. Skinner, G. C. Steel, O. Walker, and to the six candidates whose names were printed in the report of the meeting of the Council of the Royal College of Surgeons published in our issue of January 22 (p. 209).

Lectures

The following lectures will be delivered at the College, Pall Mall East, S.W., all at 5 p.m.

The Milroy Lectures on "The Public Health Aspect of Heart Disease in Childhood" by Dr. B. E. Schlesinger on February 24 and March 1; the Goulstonian Lectures on "Some Deficiencies of Nutrition and their Relation to Disease" by Dr. C. C. Ungley on March 3, 8, and 10; the Lumenian Lectures on "Pain of Central Origin" by Dr. George Riddoch on March 15 and 17; and the Oliver-Sharpey Lectures on "Recent Observations on the Morphology of the Neuron, and on the Changes which it Undergoes in Disease," by Dr. J. G. Greenfield on March 22 and 24.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Special Lectures

A special lecture on "The Prehistoric People of Mount Carmel" will be delivered by Sir Arthur Keith, M.D., F.R.S., F.R.C.S., Master of the Buckton Browne Farm, in the theatre of the College, Lincoln's Inn Fields, W.C., on Monday, February 14, at 5 p.m.

Dr. W. E. Gye, Director of the Imperial Cancer Research Fund, will deliver a special lecture on "Some Recent Work in Experimental Cancer Research" in the theatre of the College on Wednesday, February 16, at 5 p.m.

Fellows and Members of the College are invited to attend the lectures. Students and others who are not Fellows or Members of the College will be admitted on presenting their private visiting cards. Tea will be served before the lecture.

The lecture by Professor P. B. Ascroft on an experimental study of the surgical treatment of arterial hypertension, arranged to be given at the College on February 11, has been postponed.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—N. D. Cousins, T. C. Hallinan, B. M. Hulce, C. K. Westropp.

MEDICINE.—P. H. Beamish, A. W. Frankland, D. H. Fowler, T. C. Hallinan, B. T. Jones, G. E. King-Turner, C. K. Westropp.

FORENSIC MEDICINE.—P. H. Beamish, A. W. Frankland, D. H. Fowler, T. C. Hallinan, C. K. Westropp.

MIDWIFERY.—A. N. Boyle, G. H. L. Bullimore, A. W. Frankland, A. J. Patenall, M. Tombuk, T. G. Viljoen, C. K. Westropp.

The diploma of the Society has been granted to D. H. Fowler, B. T. Jones, and C. K. Westropp.

The Court of the Society has awarded the Gillson Scholarship in Pathology for 1938 to Dr. R. H. S. Thompson of the University of Oxford and Guy's Hospital, who is at present working in the Rockefeller Institute Hospital (corrected announcement).

Medical Notes in Parliament

Both Houses of Parliament resumed on February 1.

The Parliamentary Medical Committee will meet on February 8. An open meeting of M.P.s is arranged under its auspices on February 17, at which Lord Horder will speak about the Empire Rheumatism Council.

The Blind Persons Bill passed through committee in the House of Commons on February 1.

Population (Statistics) Bill

In the House of Commons on February 1 the Population (Statistics) Bill was considered in committee. The object of the Bill is to extend the scope of the particulars which can at present be asked for on the registration of a birth, stillbirth, death, or marriage, and so to provide the statistical evidence needed for practical consideration of the problems of the future population of Great Britain to which the decline in the birth rate has given rise.

Sir KINGSLEY WOOD moved a number of amendments which had been put down in the light of a previous discussion on the Bill. He said that instead of the ordinary census procedure, to which objection had been taken, it had been decided to substitute a limited number of defined but simple matters of which particulars might be required. The person who would supply the particulars would be required to give only the facts within his or her knowledge. If such person had not the knowledge a statement to that effect would relieve that person from any obligations in the matter. Such particulars were to be furnished as from July 1 next.

One amendment would ensure that the information given would be secret and privileged. The particulars to be asked for would supply information about the degree of fertility of a mother, childless wives, and matters requisite for statistical purposes. He understood that there was no objection among members of the House to these particulars being asked for. Certain supplementary lines of investigation could also be made on the information obtained. Particulars furnished of a mother's issue, living or dead or stillborn, would help in the further investigation of the high rate of infantile mortality. Cancer in women had been studied from the point of view of married and unmarried women, and the investigation could now be carried further from the aspect of childless wives and those who had produced children.

He was prepared to accept an amendment to fix the period of operation of the measure at ten years. It might be that during the next few years experience would show how far these matters sufficed, and whether any alteration or modification of the scheme was desirable. Also, before the end of ten years they might have sufficient information on which the whole matter would have to be considered in its larger aspects.

Sir FRANCIS FREMANTLE said that the question was whether the Bill had not been cut down too much. The House had decided to restrict inquiries to the smallest limits. If it was found that there was too much restriction an amending Bill would have to be prepared. The real seriousness of the depopulation question was not understood by the House. They would be running the risk of losing precious years if they did not get the vital statistics which were required.

The amendments moved by Sir Kingsley Wood were agreed to. It was also agreed that registration officers, who were paid on a fee basis, should, after payment of 2s. 6d. an entry for the first twenty entries, be paid at the rate of 1s. 5d. per entry, whether of a birth or a death, instead of 1s. for a birth and 1s. 3d. for a death, as at present.

Mr. O. LEWIS also moved an amendment providing that the Bill should continue in force until June 30, 1948, and no longer, unless Parliament otherwise determined. Sir FRANCIS FREMANTLE said that this was a most astonishing amendment. They might as well abolish the whole registration scheme of the country in ten years' time. This was a very valuable

measure, and it was childish to bring it to an end after ten years.

Sir KINGSLEY WOOD accepted the amendment. He said that following the experience of other countries it might be necessary before the end of ten years to examine the larger questions which would be involved in regard to population.

The amendment was agreed to and the committee stage was concluded.

Deaths and Disablement from Silicosis

On February 1 Sir SAMUEL HOARE, in reply to Mr. J. Griffiths, said that in 1937 there were 643 applicants to the Medical Board for certificates of disablement or suspension under the Various Industries (Silicosis) Scheme from coal miners in Great Britain; 286 certificates were granted. In 1936 there were 674 applications, and 319 certificates were granted. From anthracite mines there were 230 applications in 1937, 132 certificates being granted; and in 1936 the figures were 319 and 182. In 1937 seventy-two deaths were certified as due to the disease, against seventy-seven in 1936. In anthracite mines there were thirty-five deaths in 1937 and thirty-nine in 1936.

Notes in Brief

Sir Kingsley Wood has received reports of water shortage of varying degree from four boroughs, four urban districts, and parts of sixteen rural districts. In seven of these, additional supplies have been provided, and in the remainder the Minister is in communication with the local authorities on the remedial measures required.

Mr. W. S. Morrison stated on February 1 that the technical report of the Committee on Poultry Diseases would be generally available in the course of a week.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The Chancellor has received from the Rockefeller Foundation a letter stating that action has been taken to provide to the University of Cambridge up to £8,000 towards support of research in its Department of Experimental Medicine for the five-year period January 1, 1938, to December 31, 1942, the amount available in any one year of the grant not to exceed £1,600. It is intended that these funds shall be used for the salaries of a pathologist and a psychiatrist, and for supplementing the amount which the radiologist receives from Addenbrooke's Hospital.

The Board of Management of the Frank Edward Elmore Fund will shortly award a studentship for research in medicine. These studentships are open to male graduates of any university who were born in any country within the British Empire other than Scotland. The student appointed will work in the Department of Medicine under the direction of the Regius Professor of Physic. The commencing salary will be £300 a year, and the appointment will be for two years in the first instance. Further information may be obtained from the Regius Professor of Physic, Department of Medicine, University of Cambridge, to whom applications, together with three testimonials, a statement of previous appointments, and copies of published papers should be sent not later than February 28.

On Monday, February 14, at 5.15 p.m., Professor J. H. Hutton will give an inaugural lecture on "Anthropology as an Imperial Study" in the theatre of the Arts School.

UNIVERSITY OF LONDON

At a meeting of the Senate, held on January 26, with the Vice-Chancellor in the chair, it was reported that Mr. P. H. Mitchiner, M.D., M.S., F.R.C.S., had been appointed by Convocation, on the election of the graduates in medicine, to be their representative on the Senate for the remainder of the period 1937-41, in place of Dr. W. G. Spencer, resigned.

The William Julius Mickle Fellowship for 1938 was awarded to Dr. Leonard Colebrook.

UNIVERSITY OF BIRMINGHAM

Three William Withering Lectures on chemical transmission of the effects of nerve impulses will be given in the large theatre

EPIDEMIOLOGICAL NOTES

Typhoid Fever

The addition of 54 cases not previously reported, the majority of which originated in other areas but had some connexion with the Croydon outbreak, brings the total for primary and secondary cases to 344, compared with 290 cases recorded last week. Two additional deaths during the week bring the total number to 43 at the time of going to press. Three cases of typhoid fever, two of which were in the same family, have been reported in Chatham during the last fortnight, with one death. Water pollution has been excluded as the source of the outbreak, and it is possible that infection took place in some other area. Since January 20, 14 notified cases of typhoid fever, since confirmed, with three deaths, have been reported in the Bridgwater and Highbidge areas in Somerset. The inhabitants of these areas were advised by broadcast during last week-end to boil all water and milk supplies before use. During the same period 10 cases have been reported in a Pembrokeshire outbreak, which originated at Solva and St. David's. A male adult patient has died from typhoid fever in the Scilly Isles. Despite these fresh outbreaks of typhoid in three different areas the disease is less prevalent in England and Wales than in the previous week, and the figures are much lower than those for the corresponding week last year and than the median value for the last nine years.

Dysentery

Dysentery figures show a considerable drop in England and Wales—200 in the week under review compared with 288 in the previous week—but the incidence is still high compared with the corresponding week last year, when no more than 21 cases were notified. Swindon is the only centre in which a fresh outbreak of any magnitude has appeared; in the previous week only 5 cases were notified, but in the present week an explosive outbreak involving several hundred cases has been reported. The mode of infection and spread of dysentery continues to baffle all investigation; examination of milk and water usually yields negative results, but uncooked vegetables remain a likely source. The characteristic mildness of the disease facilitates spread, as it encourages lack of observance of the elementary rules of personal hygiene.

Influenza

The figures for influenzal pneumonia in England and Wales show an appreciable reduction as compared with those for the preceding week, the figures being 1,321 against 1,647, and very much lower than in the corresponding week last year, when there were 3,135 cases. A similar reduction was observed in the figures for London—117 against 159 for the previous week, and 327 for the corresponding week last year. The figures of deaths from influenza show an even more pronounced decrease as compared with last year; for England and Wales the numbers were 1,137 and 73 respectively, and for the county of London 273 and 12 respectively.

Measles

In Belfast 832 cases of measles were notified during the week under review compared with 567 in the previous week. The Glasgow figures show an appreciable decrease—1,077 against 1,409—while in Edinburgh there was a proportionate decrease—214 against 327. In Manchester 832 cases were reported during the week under review compared with 750 recorded last week. As in the previous week the daily number of measles cases admitted to the L.C.C. fever hospitals varied from 20 to 30, the average being 25; during the same week the average daily admissions for diphtheria and scarlet fever were 29 and 22 respectively. The deaths from measles in England and Wales rose during the week from 44 to 48, but in London there was a decrease of six on the figure of 9 for the previous week.

Medical News

Sir Walter Langdon-Brown will give a lecture on "The Contribution of Adler to General Medicine" before the Medical Society of Individual Psychology, 11, Chandos Street, W., on Thursday, February 10, at 8.30 p.m. Visitors are invited.

At a meeting of the Pharmaceutical Society of Great Britain to be held at 17, Bloomsbury Square, W.C., on Tuesday, February 8, a lecture on "Modern Points of View and Methods in Pharmacognosy" will be given by Dr. R. B. Wasicky, professor of pharmacognosy in the Pharmaceutical Institute of the University of Vienna. Professor Wasicky was awarded the Hanbury Medal last year, and this occasion is being taken to present the medal to him. The chair will be taken by the president at 8.30 p.m.

In our advertisement columns this week the University of Manchester invites applications for the Sir Henry Royce Research Fellowship. The Fellowship, which is open to graduates of a British University only, is for research on either "The Common Cold: Its Nature, Prevention, and Cure" or "Influenza: Its Nature, Prevention, and Cure," and is of the value of £500 per annum tenable for a period of three years. Applications should reach the registrar of the University not later than February 28.

The dinner of the Durham University Society (London) was held at the Florence Restaurant on January 27. The president, Lord Cadman, took the chair. Dr. Nathan Raw proposed the toast of "Alma Mater," and Miss E. Rathbone, M.P., the toast of "The Society." Among the medical graduates attending the dinner were Professor J. W. H. Eyre, Mr. R. Christie Brown, Colonel A. H. Proctor, and Professor G. Grey Turner.

The twentieth anniversary of the death of Lieutenant-Colonel John McCrae, C.A.M.C., consulting physician B.E.F., France, was commemorated on January 29 at the British military cemetery at Wimereux. John McCrae graduated in medicine at the University of Toronto in 1898. He was co-author with the late Professor Adami of a well-known textbook on pathology, and contributed many articles on pathology and clinical medicine to the medical journals. He is best known to the world at large as the author of the rondeau "In Flanders Fields." Among the wreaths laid on his grave last Saturday was one of Flanders poppies.

Dr. Haven Emerson, professor of public health, College of Physicians and Surgeons, Columbia University, New York, was given an honorary doctor's degree at the recent celebration of the centenary of the foundation of the University of Athens.

The fiftieth anniversary of the Institute of Morbid Anatomy at Tokyo has recently been celebrated under the presidency of the rector, Professor Magayo.

Dr. William M. Guilford of Lebanon, Pennsylvania, said to be the oldest living physician in the United States of America and probably in the world, celebrated his 105th birthday on November 26th, 1937. His grandfather lived to be 95 and his father to be 94.

Dr. W. W. Adamson (Lincoln's Inn) and Dr. G. V. Craine and Dr. J. J. O'Donoghue (Gray's Inn) were called to the Bar on January 26.

The December number of *Medical Classics* is devoted to William Withering, a biographical sketch and a bibliography being followed by a reprint of his *Account of the Foxglove*, 1785. This is now one of the scarcer medical classics, the few copies which turn up occasionally on the market fetching approximately £50.

According to recent statistics, in the spring of 1937 there were 55,259 medical practitioners in Germany, of whom 6,713 (12.1 per cent.) were in Berlin. Bavaria came first with 6,760 doctors, the Rhine province came next to Berlin with 6,335, followed by Saxony with 4,030.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended January 22, 1938. Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for : (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for : (a) The 125 great towns (i) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns (ii) in Eire. (e) The 10 principal towns (iii) in Northern Ireland.

A dash — denotes no cases ; a blank space denotes disease not notifiable or no return available.

Disease	1938					1937 (Corresponding Week)					1928-36 (Median Value Corresponding Weeks)

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

101 Auricular Thrombosis in Mitral Stenosis

H. SCHÖNBERG (*Med. Welt*, December 18, 1937, p. 1777) reports two cases of auricular thrombosis in mitral stenosis. The onset of the sclerotic process in the left auricle in the presence of rheumatic valvular changes coincided with the healing of the rheumatic inflammation of the auricle. This and the loss of elasticity of the auricular wall resulted in an extensive auricular thrombosis, which also spread into the vessels and was the cause of secondary aneurysms in the pulmonary veins and of secondary autochthonous thrombosis of the pulmonary arteries.

102 Poradenitis Venerea

H. LÖHE and H. SCHLOSSBERGER (*Med. Klinik*, October 22 and 29, 1937, pp. 1427 and 1471) point out that poradenitis venerea or lymphogranuloma inguinale is identical with Nicolas-Favre disease, climatic bubo, esthiomene of females, and the so-called fourth or sixth venereal disease. Commonest in tropical and subtropical regions, but occurring in all European countries (notably in France), it is almost always transmitted by coitus. Although the causative organism is a filter-passing virus difficult to culture *in vitro*, exact diagnosis is possible by means of Frei's cutaneous allergic reaction; transmission to apes and other species is possible by intracerebral or intraperitoneal injection, and the virus grows *in vivo* in tissues of mesoblastic origin. The primary sore, which is rarely seen, commonly occurs on the prepuce or coronary sulcus, in herpetic form, but may be intra-urethral. Löhe and Schlossberger have found the Frei reaction negative in some cases at this stage. Pyrexia and malaise in the following stage may be very slight; scarlatiniform, erythematous, or urticarial eruptions may occur. Inguinal adenitis follows in a few weeks. Of the two main clinical types encountered the form in which there is chronic adenitis of the superficial and deep inguinal glands, usually with suppuration and often the formation of fistulae, is seen eight times more frequently in men than in women; in women it is more usual to find ano-genito-rectal elephantiasis, often with rectal stenosis. In a very large proportion of cases of the genito-rectal syndrome there is a history or serological evidence of lues, and the Frei reaction is then commonly negative—becoming positive, however, after a few weeks of antisyphilitic medication. Early treatment is important for the prevention of lymphatic obstruction. In addition to rest and hot applications, repeated punctures of softened glands or surgical excision of certain enlarged or suppurating glands is often called for, and cuts short the course of the malady. Löhe and Schlossberger do not advise radical excisions, which promote lymphatic obstruction, and have seen no benefit from x-ray therapy in early cases. Rectal stricture may necessitate a temporary colectomy. Chemotherapeutic measures are of great assistance—antimony tartrate, gold in the form of solganol, and certain organic arsenical compounds containing antimony being the most useful. Recently intravenous injections of Frei antigen have been used successfully in treatment by HELLERSTRÖM and by the writers.

103 Agranulocytosis due to Prontosil

J. L. GOMPERTZ, J. GROEN, and S. J. DE VRIES (*Nederl. Tijdschr. Geneesk.*, December 11, 1937, p. 5932) refer to the fatal cases recorded by Borst and by Young (*British Medical Journal*, 1937, 2, 105) following the use of prontosil, and record a third case in a man aged 63 suffering from pyelitis. Examination of the blood showed

only 300 leucocytes per c.mm., while films showed not a single polymorphonuclear leucocyte, only lymphocytes and a single monocyte. The red cells and blood platelets were normal. In all three cases agranulocytosis developed about the eighteenth day of treatment. In none of the cases was the dose unusually large. In Borst's case the patient was given at first 1.8 grammes and later 2.4 grammes daily. Young's patient had 3 grammes, and in the present case the average dose was 0.9 gramme daily. The writers deprecate the use of prontosil when it is not strictly indicated, and stress the need for careful clinical and haematological supervision of every patient who is taking prontosil, as well as the importance of not continuing the drug for more than ten or twelve days at a time.

104 Prognosis of Lobar Pneumonia

K. HERMAN (*Med. Welt*, December 11, 1937, p. 1748) divides the course of lobar pneumonia into three periods, of which the first supplies no information about the possible course of the disease. The most decisive moment is the time between the second and third periods, which usually corresponds to the fifth to the eighth day. Prognosis is based on the type of the bronchial breathing. In those cases which are moving towards recovery the bronchial breathing either remains the same or may even decrease, sometimes in spite of an accentuation of the other symptoms. This rule applies only to lobar pneumonia, not to the other types of pneumonia or bronchopneumonia, and does not take into consideration possible complications.

Surgery

105 Cavernous Sinus Infections due to Nasal Furuncles

J. STEINMANN (*Schweiz. med. Wschr.*, December 11, 1937, p. 1189) alludes to the high mortality in young people of nasolabial infections extending to the cavernous sinus; to the necessity for abstaining from local surgical intervention, apart from evacuation of a fluctuating abscess; and to the difficulty of venous ligation in this region. Other treatments employed with some success have been the intraspinal injection of ultrafilterable bacteriophage and the intracarotid injection of rivanol. Steinmann records two cases successfully treated by the injection of anti-staphylococcal bacteriophage into the carotid. In the first, a man aged 25 had chemosis, orbital oedema and ocular protrusion pointing to incipient cavernous sinus thrombosis following a staphylococcal furuncle at the root of the nose; three injections of 3, 20, and 20 c.cm. respectively of an autobacteriophage were made into the common carotid artery. The second case was that of a diabetic, aged 68, who had an alar furuncle after an attack of bronchial pneumonia. If bacteriophage injections are being used, no local or general antiseptic treatment and no irradiations with x rays should be given at the same time; it is useless to continue the injections from the same strain should the second or third fail to induce improvement.

106 Deaths from Pulmonary Embolism

V. WESTBERG (*Uppsala Läk.Fören. Förh.*, November 30, 1937, p. 101) has investigated the 104 deaths from pulmonary embolism which occurred in the period 1922 to 1934 in the University Surgical Hospital in Uppsala. He has also studied the thromboses which occurred in this hospital in 1934, definite cases of thrombophlebitis being excluded and only cases of distant thrombosis being considered. As many as seventy-five of the 104 deaths were

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

Dublin; telephone 62550 Dublin).

QUERIES AND ANSWERS

The "Emergency Bag"

"EX-SERVICE" writes: I should be grateful if readers would give their opinion as to what they consider the minimum contents of the general practitioner's "emergency bag."

Incapacitating Diarrhoea

"MEDICO" writes: My own experience may be of use to "Stug" and "Emdee." If my bowels are moved every day a loose and toxic diarrhoea develops, and the more fluid I drink the more am I liable to this. I find it best if my bowels are moved three or four times a week (every other day or so), and I therefore limit my fluid intake to this end—four cups of fluid a day in the winter. I naturally avoid foods with a good deal of roughage—for example, cabbage, lettuce, etc. The condition may be due to a relative lack of power of absorbing water from the colon. During the summer I can drink much more, on account, no doubt, of the increased sweating from the skin. I don't rely on drugs.

After-treatment of Circumcision

Mr. V. R. CLIFTON, Ch.M., writes in reply to "A.B.C." (January 29, p. 264): I have had considerable experience of adult circumcisions, and in about 50 per cent. of the cases sensitivity of the glans penis has been a troublesome post-operative symptom. I have found percainal ointment (Ciba Ltd., 40, Southwark Street, London, S.E.1), which contains 1 per cent. percaine, to be most efficacious in these cases. Its analgesic effect lasts about eight hours, and it should be applied two or three times a day until the glans loses its sensitivity. A smear of this ointment applied to the glans penis before coitus is also most helpful to those patients who complain of premature ejaculation.

Squatting Position in Defaecation

"D. M. M." in reply to "Vis Medicatrix" (*Journal*, January 22, p. 213), reports that several years ago he bought what he thinks may be the "simple device," fitting round the base of the pedestal, which "Vis Medicatrix" asks for. He bought it from P.A.F.R. Co. (Proper Adjustable Foot Rest Co.), Newark-on-Trent, Notts. "D. M. M." still uses it.

Nocturnal Twitching of Lower Limbs

"M.O." writes: With reference to the letter by "Wilts" concerning nocturnal twitchings, I have a patient suffering from what appears to be the same complaint. She is a woman of 40 who has had these twitchings all her life, but only when she is very tired; they usually start when she sits down after

dinner. The only thing that stops them is for the patient to get up and walk about. If she goes to bed they do not keep her awake, but sometimes if she is wakened with a start the twitchings begin again. They are not visible movements, but, as she describes them, "feel like an inward creepiness." Apart from this her health appears to be extremely good.

Income Tax

Employment by Steamship Line

"STEAM" is a British subject. He has accepted an appointment as ship surgeon in a Canadian line, and intends to make his future headquarters in Canada, though he will probably spend about forty-five days a year in the United Kingdom. He has hitherto lived with his mother, but this will no longer hold good.

** The facts are distinctly similar to those in the case of Commissioners of Inland Revenue v. Combe, decided by the High Court in 1932. Mr. Combe, who had been resident in the United Kingdom, left to take up an appointment for three years in New York, but visited the United Kingdom each year on his employer's business. During that time he had no fixed place of abode here, but resided in hotels when in this country. The High Court held that the Commissioners who had discharged the assessment on Mr. Combe had evidence to support their decision, and declined to interfere. We suggest that our correspondent might put forward this case as similar to his own if he is asked to pay United Kingdom tax on his emoluments.

LETTERS, NOTES, ETC.

Uniovular Triplets

Dr. JAMES A. WATERMAN (Colonial Hospital, Port of Spain, Trinidad) sends the following account of a case of uniovular triplets. The mother, who is aged 35, has had eleven pregnancies; all the children except the second and third are alive and normal. The second pregnancy ended in abortion, and the third child died at the age of 11½ months. The grandmother had had fifteen children, including two sets of twins. Labour pains started at 2 a.m. on October 2, 1937. The first membrane ruptured before admission to hospital. A female infant was delivered at 7.50 the same morning, L.O.A.; weight 5 lb. 10 oz., length 18½ inches. The second membrane ruptured at 8.5 a.m.; the infant—a female, footling presentation—weighed 4 lb. 8 oz. and measured 18 inches. The third membrane ruptured, and the patient was delivered at 8.20 a.m. of a female infant, the presentation being a R.O.A.; the weight was 4 lb. 6 oz. and the length 18 inches. The placenta was delivered with membranes complete at 8.30 a.m. There was one placenta, one chorion, and three amnions.

Treatment of Impetigo

Dr. A. W. DAVISON and Dr. T. D. CULBERT (Manchester) write: During 1937 we treated a considerable number of cases of impetigo with mineroleum zinci & ichthammol (Woolley), containing 2½ per cent. ichthylol and zinc oxide. We were so impressed with the results of this treatment in private patients that we prescribed a similar ointment for panel patients. The longest time taken for a complete cure was ten days, and in most cases the lesions cleared up in less than a week. We instructed the patients to apply the ointment night and morning after removing any crusts with cotton-wool soaked in olive oil, and to refrain from washing the face during treatment.

Oxygen Want and Oxygen Therapy

In a leading article on this subject (*Journal*, January 29, p. 235) we stated that "even the simplest tents . . . cost up to about thirty to forty shillings a day to run." The British Oxygen Company Limited now write: "An oxygen tent uses anything from 3 to 7 litres a minute. Allowing for occasional flooding and wastage and for the delivery and collection of cylinders, the cost to a hospital of running a tent, buying directly the appropriate cylinders, should be 15s. a day, and to hospitals which use their oxygen from batteries of cylinders through pipe-lines, considerably less."

The Slough Social Centre

A typist's error in our article on this subject last week (p. 249) made a phrase near the foot of the first column read "skilled medical supervision and national health insurance." It should have read "school medical supervision."

therapy, including neosalvarsan, parenteral chemotherapy, antipyretics, change of climate, and x-ray irradiation of the spleen, has been tried by various authors with greater or less success. Curschmann strongly advocates specific vaccine therapy. He has used polyvalent *Brucella* strains with success for many years. Small doses producing a mild reaction in the patient are better than large doses. He suggests the intramuscular injection of dead polyvalent *Brucella* strains in initial doses of 1 to 5 millions per c.cm., with increasing doses at two- to three-day intervals until the daily dose is 20 millions. It is unnecessary to test the patient's reaction before treatment. Of fifty cases thus treated thirty-six were completely cured, three were improved, five were unaffected, and in six cases the results were not known. Curschmann states that cases treated early give the best results. Even elderly patients may be successfully treated. Cases with grave complications are often improved by specific vaccine therapy, and success has also been obtained in old-standing cases with anaemia and enlargement of the spleen and liver.

Diseases of Children

112 Periodic Paralysis

JAMES B. GILLESPIE (*Arch. Pediat.*, October, 1937, p. 569) describes in detail the case of a boy subject to this rare condition. His walking was normal except for periodic attacks of weakness of the legs, which became useless for ten to twenty minutes at a time. The attacks came on three or four times a day, generally when he was fatigued, the child falling down and being unable to get up. All reflexes were lost during the attacks. The legs only were affected and there was no pain or loss of sensation. The aetiology of the condition is unknown, but the periodicity makes it unlike any other condition.

113 Local Vaccine Treatment of Nasal Suppuration

F. BLOTTA (*Rev. méd. lat.-amer.*, August, 1937, p. 1240) has treated infants and children successfully for suppurative rhinitis and ethmoiditis by the intranasal application of a combination of Besredka antiviral (culture-broth) and Herelle bacteriophage filtrate. A stock preparation was used, and applied on gauze in infants or by retrograde insufflation in children. Such treatment was either effective by itself or found to be of use before and after surgical treatment—for example, removal of adenoids. In maxillary sinus suppuration in adults, when combined with lavages after antral puncture, it occasionally rendered major operative measures unnecessary.

114 Cerebral Tumours

R. O. STERN (*Arch. Dis. Childh.*, October, 1937, p. 291) has investigated 102 cases of cerebral tumour, which were observed during a period of fifteen years in children under the age of 12; over one-half arose during the first five years of life. There was no difference in the sex incidence. Fourteen of the tumours, the existence of which was verified at necropsy, occurred during the first two years of life. An important finding was that tumours were twice as common below the tentorium as above it. A histological study was made of fifty-five tumours, two-thirds of which belonged to the glioma group. Only one solitary tuberculoma was found. There were six examples of malignant gliomata. Glioblastoma multiforme, a tumour which commonly occurs in the cerebral hemispheres of adults, and four ependymal tumours are included in the series. The more benign tumours were found at an earlier age, and only a small proportion of the malignant types were seen in children of less than 5. The hopelessness of most cases was evident, and was due to the situation of the tumour, which all too often offered insuperable difficulties to a surgical approach. The absence of pituitary tumours is surprising, but this

is accounted for by the age of the patients in this series. Pituitary tumours are found more commonly in children over 12 years of age; Cushing reported no less than twenty such cases in a series of 154 cerebral tumours.

115 Antirachitic Action of Irradiated Yeast

H. HOFFMANN-WÜLFING (*Arch. Kinderheilk.*, 1937, 112, 4, 227) has investigated the antirachitic action of irradiated yeast in children. He found that a daily dose of 6 grammes of the irradiated yeast was sufficient to cure active rickets within six weeks; the total dosage of yeast was 250 grammes. Clinical and radiological improvement was already noticeable after three weeks. To possess such antirachitic activity 1 gramme of this yeast must contain at least 2,000 protective antirachitic rat units. It is quite possible that a more active preparation of irradiated yeast may be discovered, but at present the doses of yeast are necessarily very high.

116 Phrenic Evulsion

V. MONACO and L. DI VITO (*Ann. Ist. Carlo Forlanini*, August, 1937, p. 21) record their observations on twenty-one cases of pulmonary tuberculosis in children aged from 2 to 12 years treated by phrenicectomy at the Carlo Forlanini Institute in Rome. In seventeen cases the lesions were confined to one lung, while in the remainder both lungs were involved. Of the unilateral cases thirteen were cured and four showed some improvement, and of the bilateral cases two died and two became worse. The authors come to the conclusion that phrenic evulsion is indicated in unilateral forms of inactive pulmonary tuberculosis with a tendency to sclerosis, and that it may be combined with, or be employed after, the induction of an artificial pneumothorax; it may be used also in cases of haemoptysis when it is impossible to induce an artificial pneumothorax.

Obstetrics and Gynaecology

117 Leucorrhoea and Vitamin Deficiency

STÄHLER (*Dtsch. med. Wschr.*, October 22, 1937, p. 1609) has investigated at the University Maternity Hospital of Frankfurt a.M. the possibility of there being a connexion between leucorrhoea and vitamin deficiency. This study, conducted between April, 1935, and March, 1937, was limited to 1,025 cases of non-specific leucorrhoea, and the dates of onset month by month were noted. No case of leucorrhoea was included in this study if there was some specific cause for the discharge such as cancer, gonorrhoea, polypi, tears of the cervix, etc. When these non-specific cases were classified according to the months in which they began no instructive curve could be drawn, but when the cases were classified according to whether the leucorrhoea was or was not associated with a trichomonas infection divergent monthly curves emerged, the trichomonas cases showing a peak in the summer, the non-trichomonas cases a peak in the winter. During the winter months there were between two and three times (2.6 times) as many cases of non-trichomonas leucorrhoea as in the summer months, while between April and September there were between two and three times (2.4 times) as many cases of trichomonas infection as in the winter months. In co-operation with the Meteorological Institute of Frankfurt, the author has studied the possibility of these observations depending on such factors as humidity, atmospheric pressure, temperature, etc., but the only correlation that could be established concerned the hours of sunshine and ultra-violet radiation, with which true non-specific leucorrhoea was inversely and trichomonas leucorrhoea directly proportional. The author associates this observation with his clinical experience of the good effects of quartz-light treatment on non-trichomonas leucorrhoea. As for the comparatively

post-operative, and forty-nine of the seventy-nine cases of thrombosis were also post-operative. In the period under review there were 19,574 patients operated on and 18,055 not operated on. The mortality from pulmonary embolism was 0.38 per cent. for the first group and only 0.16 per cent. for the second, and for both groups it was 0.28 per cent. In 1934 the morbidity from thrombosis for the patients operated on was 2.63 per cent., whereas it was only 1.79 per cent. for the patients not operated on; for both groups it was 2.24 per cent. In as many as eighty of the 104 cases death was sudden, and only in the remaining twenty-four cases did signs of thrombosis give warning of the fatal embolism. The choice of anaesthetic did not appear to affect the embolism rate, which was 0.38 per cent. for operations below the diaphragm (seventy deaths) and only 0.06 per cent. for operations above the diaphragm. It seemed to be immaterial whether, among the operations below the diaphragm, the peritoneal cavity was opened or not. Most of the deaths occurred between the fourth and tenth days after operation. Not one of the 400 patients suffering from some form or other of thyroid disease died of pulmonary embolism. There was no sex inequality with regard to either thrombosis or fatal pulmonary embolism, but the frequency of both rose with age. The fact that the mortality was twice as high in the private as in the public wards could be traced to the comparatively high age of the patients in the former. The author could not find any marked rise in the frequency of these conditions in the period under review.

107 Urethral Diverticula

J. RIVOIR (*Zbl. Chir.*, November 13, 1937, p. 2612) recommends the examination of the urethra in every case in which there is a persistent urethritis following an operation for the relief of a urethral stricture. In such cases the examination usually reveals local changes above the site of the stricture, commonly diverticula and pseudo-diverticular formations. The condition almost always responds to appropriate local treatment. The author makes use in such cases of electrocoagulation, and claims permanent cures.

108 Congenital Torticollis

J. FOGED (*Ugeskr. Laeg.*, December 9, 1937, p. 1316) has re-examined 117 of 131 patients operated on for congenital torticollis between 1920 and 1935. As many as 111 were operated on in childhood, and nineteen were under the age of 5. Of the 117 re-examined, only six were adults at the time of operation. There were sixty-seven females to fifty males, and sixty-five right-sided to fifty-two left-sided cases. The 117 patients were classified in four groups according as the torticollis was slight (eight cases), moderate (fifty-nine cases), severe and complicated (forty-one cases), or had relapsed after an earlier operation (nine cases). General anaesthesia with ether was always employed, and the operation was an open tenotomy of the sterno-mastoid at the seat of its contracture. Great importance was attached to performing the operation as radically as possible. After over-correction in hospital, exercises after discharge were continued for six months to two years. There were no operative deaths, and the immediate results were, with only one exception, satisfactory. On re-examination from one to sixteen years after leaving hospital the patients were classified in three groups, in the first of which there were 100 patients for whom it could be claimed that the operation had been perfectly successful. In the second group, containing thirteen patients, the results of the operation were partially marred by such flaws as restricted movements of the head, lack of symmetry of the face, slight rotation of the head to the healthy side and flexion towards the diseased side, persistence of some deformity of the spine, a disfiguring operation scar, etc. In the third group were four patients who had relapsed so as to be no better off than

before. The four main lessons the author extracts from this study are that (1) the operation must be as radical as possible, (2) it should not be attempted till the patient is about 4 years old, (3) a position of over-correction of the head should be maintained throughout the patient's stay in hospital, and (4) after-treatment should be prolonged and conscientiously followed.

Therapeutics

109 Hormone Therapy of Cryptorchidism

R. ERCOLE and A. FORT (*Ann. Chir.*, Rosario, September, 1937, p. 280) discuss the question of hormone therapy in cryptorchidism. They use the anterior-pituitary-like principle obtained from the urine of pregnant women, as they have found it to be superior to that prepared from the fresh gland. After a brief review of the literature and a short discussion on the mode of action of this treatment and the results obtained by others, the authors describe eight cases of their own (seven children and one adult) which they treated by this method. Five of these cases were completely successful, the testes descending to the bottom of the scrotum. Of the three remaining cases, one ceased to attend after a partial success and two were operated on; but even in these cases the testes descended quite easily after the resection of a few adhesions, and the cord was found to be longer than was necessary for the testes to reach the bottom of the scrotum, which, as the authors point out, is by no means usual in similar cases. They therefore suggest that hormone therapy should be tried in all cases of undescended testis before resorting to surgical measures, though they point out that the treatment is too recent for definite conclusions to be drawn.

110 Bronchial Asthma

W. H. BROWNING (*New Orleans med. surg. J.*, November, 1937, p. 269) has followed up 244 cases of bronchial asthma, analysing the methods of treatment adopted and the results. For immediate treatment he advises adrenaline 1 in 1,000 solution, not more than 0.3 c.cm. being in the arm, from which part absorption can be arrested by means of a tourniquet should immediate untoward effects appear. The value of ephedrine compounds, nitrates, etc., is discussed and the use of nostrums deprecated. The patient should be nursed in a specially prepared room, as nearly allergen-free as possible, and put on a diet described by Rowe. Subsequently a complete examination is made with a view to eliminating organic disease, because it was found that seldom was asthma due solely to extrinsic factors; skin-testing for allergy is then undertaken with a view to desensitization. The analysis of the results of treatment of 244 cases reveals that the earlier the onset of asthma, and the sooner the examination is made after onset, the better the prognosis.

111 Brucella abortus Infection

H. CURSCHMANN (*Fortschr. Ther.*, November, 1937, p. 593) states that the importance of *Brucella abortus* infection has only been realized in Germany since 1927. In all cases of raised temperature the blood should be examined for agglutination with typhoid and paratyphoid bacilli and *Brucella abortus*. Some sera give an agglutination with all three. It is important, therefore, to do the complement-fixation test and the intracutaneous test in all cases of suspected infection by *Brucella abortus*. Not all cases showing positive serological and intracutaneous tests require treatment. Only manifest cases of infection come into consideration. In these early treatment is essential in order to avoid the grave hepato-lial syndrome and the attendant complications. Non-specific

STAPLES

"The finest Mattress made"

IT'S a private and personal pride to own the very best.—To own a Staples Mattress—then no matter the day, every night is a time you look forward to—hours of lingering luxury.

MENFORMON TABLETS

to reverse menopausal changes

"Finally there is one important observation that I would bring to your notice: Patients treated with oestrin for whatever complaint, frequently volunteer the information that they experience a sense of well-being. All of us suffer only too frequently from the voluble and discontented menopausal patient, with all her aches and pains, and I have been gratified by the CHANGE OF MENTAL ATTITUDE which oestrin has afforded to some of the patients, converting them almost into cheerful kindly rays of sunshine."

high frequency of trichomonas leucorrhoea in the summer months, it might be due to bathing in public baths, but the author is more inclined to trace it to conditions, favourable to the growth of trichomonas, dependent on much sunshine; and he notes in this connexion that in fifteen cases of trichomonas leucorrhoea the vaginal administration of vitamin D raised the trichomonas count and increased the inflammatory reaction of the vagina.

118 Plastic Replacement of the Endometrium

P. STRASSMANN (*Zbl. Gynäk.*, December 18, 1937, p. 2894) in 1935 reported six cases in which he had performed his operation for replacement of the mucous lining of the totally atretic uterus by utero-cervical implantation of a Fallopian tube. The ampullary part of the tube was fixed in the body of the uterus, the middle part near the internal os, the stump in the cervical canal, and the short fimbrial extremity was left free within the abdominal cavity. He now reports that one of the patients has given birth to a normal living child. The patient, then aged 20, was curetted at home, fourteen days after her first labour, for pyrexia and haemorrhage; thirteen months' amenorrhoea followed. Strassmann then found, after anterior colpotomy, in addition to right adnexal inflammation complete atresia of the uterus; the left tube, after being mobilized, was implanted as described. Regular menstruation began again forty-three days later. Subsequently the patient was divorced, but thirty months after the operation she remarried, and within two months became pregnant. The gestation continued uneventfully to six days before term, and a child weighing 2.5 kg. was delivered spontaneously after a speedy labour. The third stage was complicated by haemorrhage and partial retention of the placenta, which weighed 400 grammes, had more extensive villousities than usual, and was inserted on the anterior, posterior, and lateral walls of the reconstituted cavity. From the successful issue of this gestation in an "endometrium" of tubal derivation Strassmann infers that a similar plastic operation might occasionally be considered in sterility with amenorrhoea in young patients in whom the endometrium, while not destroyed, has ceased to function. Fuch's operation of supra-vaginal amputation of the uterus followed by implantation of the tube into the cervix has been successful in causing a reappearance of "menstruation" in seven cases of complete endometrial destruction; the average age of his patients was 37, that of Strassmann's 25.

119 Gestation after Cotte's Operation

According to M. REEB (*Gynécologie*, November, 1937, p. 617) about a dozen cases of labour after Cotte's operation of resection of the sympathetic fibres of the presacral nerve have been recorded, some by Cotte himself and some by Grisogne. The nerve contains in addition to centripetal nerves efferent sympathetic fibres, from diencephalic centres, which are not only motor to the smooth muscle of the Fallopian tubes, uterus, and vagina, but also regulate the tone of the striated muscles of the pelvic floor, perineum, vulva, and anus. Clinical experience has shown that Cotte's operation does not interfere with micturition, defaecation, or menstruation, or with normal labour. No case of ectopic gestation appears so far to have followed it. Reeb remarks that the abolition of the sympathetically regulated tonus of the striped muscles of the pelvic outlet might be expected to favour the expulsive processes of labour. Such a view is supported by his first case of pregnancy after Cotte's operation. Thirteen months after the operation, which had been performed for vaginismus in a woman aged 35, an uneventful pregnancy terminated spontaneously, with a first stage lasting six hours and a second lasting forty minutes. The muscles of the pelvic floor, perineum, and vulva offered no resistance. Reeb's second patient, a primipara aged 42, became pregnant four years after

resection of the presacral nerve, and gestation continued normally until three weeks before term (when it had to be ended by Caesarean section on account of signs of pregnancy toxæmia, the patient having only one kidney) in spite of the presence of a large interstitial fibroma.

Pathology

120 Vitamin A and Carotin in Human Milk

C. E. NYLUND (*Finska LäkSällsk. Handl.*, September, 1937, p. 733) has employed a colorimetric method under spectrophotometric control for the determination of the vitamin A and carotin content of 583 samples of milk from 357 women. It was found that comparatively low resistance to infections existed among the babies whose mothers' milk contained little vitamin A. In about 20 per cent. of cases the vitamin A content of the mothers' milk was considerably below the average, and in such cases there seemed to be good reason for supplementing breast-feeding at an early stage by carrots and cod-liver oil. The comparative lack of vitamin A in the milk was undoubtedly due to a deficiency of such sources of this vitamin as carrots, spinach, tomatoes, liver, and kidneys in the diet of the mothers. It is therefore desirable that during pregnancy and lactation mothers should be given a dietary sufficiently rich in this vitamin. Much more vitamin A was found in colostrum than in later samples of milk, and the concentration of both carotin and vitamin A in the milk was considerably reduced at the end of the period February to July, but comparatively high in September. No difference could be found in the concentration of vitamin A in the milk of primiparae and multiparae, nor in that of town and country dwellers. But the vitamin A content of the milk was comparatively low in the elderly and the asthenic, whereas it was comparatively high in the young and well-nourished. The milk of mothers developing some post-partum infection was comparatively poor in carotin and vitamin A. Considerably greater fluctuations were found in the amount of carotin than in that of vitamin A. The author doubts if more than two-thirds of the babies in this study received all the vitamin A they needed, and he considers it important that they should drain the breasts empty, as the vitamin content of human milk is highest at the end of a feed.

121 Cerebral Lipoid Reactions in Schizophrenia

H. LEHMANN-FACIUS (*Klin. Wschr.*, November 20, 1937, p. 1646) in a preliminary report states that he has found the cerebral lipoid anti-reaction to give positive results in 94 to 95 per cent. of schizophrenics, whether classified as paranoid, katatonic, or hebephrenic. The psychoses and other conditions almost invariably gave negative tests; cases of organic cerebral disease, as might be expected from the cerebral destructive processes of tumour, multiple sclerosis, etc., gave positive results in 6 per cent. of cases. A similar serological test of the cerebrospinal fluid in general paralysis has been longer known, and consists in the addition of the fluid to primary alcoholic extracts of brain. The positive test, which is characteristic in the schizophrenic, is attained by the use of a somewhat complicated two-part technique. In the first the cerebrospinal fluid, after being shaken up with ether, which is then removed, is mixed with a brain-lipoid extract, balsam of tolu being added: a positive result is shown by the occurrence, after centrifugalization, of a flocculation which resists admixture with normal saline. The second and confirmatory part consists in inhibition of this flocculation by the ethereal portion of the extract of the schizophrenic liquor. The reactions are organ-specific—that is, no flocculation results from admixture of the positive liquor with visceral extracts. It is of diagnostic importance that the test is always negative in manic-depressive psychoses.

SALTAIR SURGICAL SERVICE

Guarantee

We guarantee to alter or exchange or accept the return of any appliance without cost ordered by the Medical Profession, if not found suitable within fourteen days from date of supply.

Salt and Son Ltd.

The SALT AIR ARTIFICIAL BREAST

A welcome innovation

ALTHOUGH some form of artificial breast has been desirable for many years and in many cases, it is only comparatively recently that the need has been effectively met. THE SALT AIR ARTIFICIAL BREAST is the answer to the problem. Wearing it, a patient who has undergone amputation of the breast suffers no embarrassment, for the SALT AIR ARTIFICIAL BREAST exactly reproduces the natural line of the bust. It is very resilient, has a beautifully smooth surface, weighs only two ounces, retains its shape when wet and is easily dried so that bathing can be enjoyed with complete confidence. Firmly held within a specially shaped pocket in the Saltair Brassière, the breast cannot in any circumstances slip out of position. Alternatively, it can be sewn into the patient's own foundation garment, if preferred.

QUICK AS AN AMBULANCE—

In emergency cases the opportunity of an X-ray examination is frequently the means of saving a patient's life. In other serious cases too, examinations carried out in the patient's own home are of the greatest possible value.

Within forty minutes of the arrival of a PORTABLE X-RAY Service Car, negatives are ready for inspection. More and more doctors are now using PORTABLE X-RAY Cars for visiting private homes, nursing homes, and hospitals.

A fully descriptive booklet will gladly be sent on request to the address below.

As good as a second right hand in the surgery

Yet another tremendous advance in surgery examination lamps—the Ceiling Model Terry Anglepoise. Out of the way, yet instantly to hand at a touch, pouring its strong, penetrating, concentrated beam *right on to the spot*, without any distracting glare in the user's eyes. Will practically reach to any part of the average surgery, thus avoiding awkward light-shifting when the patient must not be moved. Leaves both hands free. A perfect examining and dressing lamp. For sheer efficiency and convenience nothing can simply approach the **ANGLEPOISE**—adjustable to 1,001 positions at a finger touch—and poised at any angle. Simply marvellous for all "close" work as it throws the clear light necessary for extreme accuracy. It can be brought as close as required. Saves on light bills—a 25 watt bulb works like a 60! Scientifically built—every part superlatively made. Chromium plated arms, tireless springs—for perfect balance. In several models. Models for fixing to wall or table, and on smooth-running castors. "A Triumph for Terry Springs." From 50/- (U.K. only). Patented at Home and Abroad.

Send to-day for full information and Booklet BMJ.

WARM, DRY BEDS FOR OPERATION AND ACCIDENT CASES

In cases of sudden emergency and for everyday use, the "Thermega" Electrically-Heated Blanket is invaluable for providing warm, damp-free beds. Hospitals and Nursing Homes throughout the country use "Thermega." It is the one proven remedy for driving out dampness and ensuring warm beds at the turn of a switch.

The "Thermega" Electric Pad for local application is ideal for relief of pain and for replacing hot water bottles.

At all good stores, chemists, electricians; or from Thermega Limited, 51/53, Victoria Street, London, S.W.1.

'Thermega'
Electrically Heated
BLANKETS & PADS

Blankets from 3 gns. Pads from 31/6. 2-Temperature Blankets for medical use, £8 10s. Single-heat Blanket, specially strengthened, from £4 4s. Various sizes and prices on application.

Insist on "Thermega." It is vital that these appliances should be made by experienced manufacturers.

The Portable Dark Room

The Pocket Dark Room slips directly over the May and similar Ophthalmoscopes and excludes all extraneous light rays. Examination is much facilitated and is possible in the brightest surroundings.

The soft rubber eye-caps conform to all eyes and ensure maximum comfort. They withstand sterilisation.

An extra eye-cap is provided to permit a working distance of 1" or 1½" between the eyes of the patient and doctor.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS

NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm gardens and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres. Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, near EXETER,

Write at once stating your requirements to the Secretary, MEDICAL CORRESPONDENCE COLLEGE, 19, Welbeck Street, W.1.

WE SPECIALISE IN POST-GRADUATE COACHING FOR ALL EXAMINATIONS.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

INCORPORATING THE ROSS INSTITUTE.

POSTS OVERSEAS FOR MEDICAL MEN

A register is kept in the School of medical men who are prepared to be considered for posts overseas, and the School is frequently asked to advise plantation and mining companies when such posts fall vacant.

The salaries offered are attractive; conditions of service are governed by standardised forms of contract; and many of the posts offer to medical men a most interesting field in which to practise their profession.

It is desirable that candidates for posts overseas should hold a diploma in tropical medicine and hygiene. The course provided by the London School for the Conjoint Board's Diploma lasts six months and the tuition fee is £40. The course may be taken from October to March or from January to June. There are generally more vacancies in the course commencing in January.

The Director of the Ross Institute is always glad to interview medical men who would like information regarding the possibilities of a career overseas if they will be good enough to make an appointment to call on him. Enquiries may be addressed to

SIR MALCOLM WATSON, Director,
Ross Institute of Tropical Hygiene,
London School of Hygiene & Tropical Medicine,
KEPPEL STREET, GOWER STREET, W.C.1.

Stammering, Cleft Palate Speech, Lispings.
39 of Miss BEHNKE, 39, Earl's Court Sq., S.W.5.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in April, 1938.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than February 28th, 1938.

HIS MAJESTY'S COLONIAL SERVICE

COLONIAL MEDICAL SERVICE.

During 1938, the Secretary of State for the Colonies proposes to select a number of Medical Officers to fill vacancies, the majority of which will occur in Tropical Africa and Malaya.

QUALIFICATIONS.—Candidates must be British subjects of European parentage, under 35 years of age, and must possess a medical qualification registrable in the United Kingdom. Preference will be given to candidates who have held Hospital or Public Health appointments, or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose and throat, venereal diseases, etc.

SALARY.—Initial salaries vary from £600 to £700, and rise by increments to a maximum of between £1,000 and £1,200.

PRIVATE PRACTICE.—Private practice is not allowed as of right, but in the case of some appointments it is permitted on certain conditions.

QUARTERS.—In Tropical Africa, free quarters, or an allowance in lieu, are provided. In Malaya, quarters are provided at an annual rental not exceeding 6% of the officer's salary.

PASSAGES.—Free first-class passages are provided on first appointment and when proceeding on and returning from leave. Assistance is also given towards family passages.
